Who Benefits from Benefits?
Municipal Consequences of Federal Cash Transfers

Arthur Alberti[†]

October 2, 2026

Abstract

Centralized welfare programs limit local discretion over eligibility and payments, yet access often depends on municipal bureaucracies. We study whether local politicians obtain electoral returns from a federally designed cash transfer when their remaining discretion lies in registration. In Brazil's *Bolsa Família*, a 2009 reform unexpectedly changed the formula assigning municipal beneficiary quotas, and a later federal revision opened additional slots during the same mayoral term. We measure the cumulative authorization change relative to the allocation implied by the previous rule. In the 2,078 municipalities where the mayor elected in 2008 sought reelection in 2012, greater federal authorization led to more new family registrations and higher realized beneficiary enrollment. The 2SLS estimate implies that 100 additional beneficiary families per 10,000 residents raise the incumbent's vote share by 1.70 percentage points. Enrollment expanded both with and without a pre-existing local welfare center (CRAS), but we find a clear electoral response only in CRAS municipalities. Within that group, the vote-share response is larger where offices report active outreach and more intensive service to *Bolsa Família* families. These patterns are consistent with electoral returns arising where municipal welfare offices bring potential beneficiaries into contact with the local administration. Federal control over eligibility and payment does not eliminate local political returns when program access still depends on municipal action.

Keywords: cash transfers; electoral returns; state capacity; *Bolsa Família*.

1 Introduction

Across the developing world, cash transfer programs have become a leading tool for reducing poverty while insulating redistribution from local political discretion. By standardizing eligibility rules, fixing benefit values by federal decree, and processing payments through centralized banking systems, these programs are designed to reduce the scope for patronage and discretionary allocation (Fiszbein and Schady, 2009). Yet access often depends on local bureaucracies controlled by elected officials. Can local politicians benefit electorally from policies designed and financed by another level of government? This is the question we address.

We study this question in the context of Brazil's *Bolsa Família*, one of the largest conditional cash transfer programs in the world.[1] Although eligibility rules, benefit size, and payments are determined by the federal government, municipalities remain responsible for identifying and registering eligible households, mostly through local welfare centers known as *Centros de Referência de Assistência Social* (CRAS). This institutional arrangement creates a narrow but important margin of local discretion: while mayors cannot alter transfer amounts, redirect funds, or withhold payments, they control the administrative pipeline through which households may gain access to the program.

This margin depended on a registration process that required active municipal effort. Identifying potentially eligible families meant locating them, conducting household interviews, and collecting documentation; municipal authorities controlled the local registration apparatus, which gave them influence over the pace, intensity, and reach of enrollment efforts.[2] In practice, two municipalities facing similar levels of underlying need could generate very different realized coverage depending on how actively the local administration pursued registration.

Our empirical strategy starts from a 2009 reform that revised the formula used to compute municipal *Bolsa Família* quotas. The program operates through federally determined municipal quotas, which set a ceiling on the number of families that can be served in each municipality.[3] A mayor elected in 2008 could expect the next adjustment

[1] By June 2006, *Bolsa Família* covered 11.10 million families, approximately 46 million people, or about 25% of the Brazilian population. By June 2015, the program supported 13.80 million families, with an average monthly benefit of R$167.15 and a budget equivalent to 0.50% of GDP.

[2] Hellmann (2015) describes enrollment as a municipal responsibility. He reports that as of September 2014, 77% of registrations were made without a home visit. Municipalities were responsible for preparing the local structure for registration, training personnel, promoting awareness campaigns, and designing *active search* strategies to reach eligible families outside the existing registry.

[3] Lindert et al. (2007) explain that *Bolsa Família* maintained municipal program quotas based on local

to follow the previous allocation rule. Instead, the federal government changed that rule in 2009 and revised municipal quotas again in 2012.[4] These revisions expanded the ceiling, not the registry. Families who were already registered could enter when new slots opened, while filling the remaining slots depended on local governments' effort to identify, locate, and register eligible families not yet in the federal database.

We combine administrative data on quotas, realized beneficiary counts, and local social-assistance infrastructure with municipal electoral data from the subsequent election. The construction of the 2009 benchmark follows Gerard et al. (2026): we apply the previous allocation rule to the information available before the reform. Our main measure subtracts that benchmark from the official 2012 quota, capturing the cumulative authorization that opened during the mayor's term.

Federal authorization created room for municipalities to bring more families into the program, and the first stage shows how they used that room. A one-standard-deviation quota shock adds 171.50 authorized slots per 10,000 residents, followed by 48.47 additional family registrations and 62.14 additional beneficiary families per 10,000 residents. Newly available slots could be filled by families already registered as well as by those registered during the mayoral term, so the two responses describe related stages of access rather than the same households. The registration response is concentrated among potentially eligible families: 43.60 additional registrations have income recorded at or below R$140 in 2012, while the estimated response above that threshold is imprecise.

Once federal authorization is shown to translate into realized enrollment, we estimate the electoral return to expanding the ceiling itself, before separating out how much of that ceiling municipalities chose to fill. For the same one-standard-deviation quota shock, the intention-to-treat estimate is 1.06 percentage points on the incumbent's vote share. This is the electoral consequence of additional federal authorization, integrating over the local enrollment response documented in the first stage.

Scaling the intention-to-treat effect by the first stage gives the electoral response to realized beneficiary expansion. A one-standard-deviation increase in instrumented enrollment, about 181.36 additional beneficiary families per 10,000 residents, raises in-

poverty estimates. Original municipal allocations were constructed by combining the 2001 PNAD with the 2000 Census, generating an initial national target of 11.20 million families when the program was created in 2003.

[4] Hellmann (2015) notes that *Bolsa Família* administered municipal quotas using estimates of poor families developed in partnership with IBGE and reports that, in 2009, the federal government refined the measurement of the target population by incorporating methodologies to capture income volatility among vulnerable households. These studies formed a major expansion of coverage, incorporating more than 1.60 million additional families.

cumbent vote share by 3.08 percentage points. Equivalently, an increase of 100 beneficiary families per 10,000 residents raises vote share by 1.70 percentage points. The positive vote-share result is robust across the main specifications and remains similar under most alternative definitions.

These electoral returns vary with the local institutions through which families seek access. Of the 2,078 municipalities in the estimation sample, 1,394 had a welfare center (CRAS) recorded before the reform and 684 did not. Both groups turned additional authorization into beneficiary enrollment, but the electoral response is clearer where families could already turn to a local welfare center. This pattern points to the welfare office as a place where families can encounter the local administration while gaining access to a federal benefit.

The activities of those centers offer a closer view of that setting. Active outreach brings staff to potentially eligible families, and municipalities reporting it show a larger estimated electoral response, although the difference from municipalities without outreach is imprecise. The *Programa de Atenção Integral à Família* (PAIF) offers another form of contact through continuing family support: a simple indicator for whether any families were reported as served does not clearly distinguish electoral responses, while centers serving more beneficiary families show a larger response than those serving fewer. Together, these patterns are consistent with electoral returns arising as potential beneficiaries encounter municipal staff during registration and subsequent support.

These findings advance three related literatures. We speak first to the political economy of cash transfer programs. Studies of social transfers find gains in government support and, in some settings, incumbent voting, although electoral results vary across designs and contexts (Manacorda et al., 2011; De La O, 2013; Imai et al., 2020). A related study by de Janvry et al. (2012) shows that mayors facing reelection incentives achieved better outcomes under the federally funded but locally implemented *Bolsa Escola* program. Their result shows how electoral incentives can shape local delivery; we examine whether the municipal work of expanding access, in turn, generates electoral returns when benefit rules and payments remain federal. Our findings show that federal control of transfers can coexist with a local political opportunity at the registration stage, where municipal staff help families enter the program.

Our paper is especially closely related to Frey (2019), but the two designs study electoral returns under different implementation regimes: Frey's intervention leaves less room for mayoral involvement, whereas ours depends directly on municipal administration. Frey exploits a discontinuity in federal funding for the *Family Health Program*, a primary-care program in which teams follow a federally specified protocol of routine

home visits to poor households. His information channel is embedded in those visits: the teams disseminate *Bolsa Família* eligibility information as part of their routine work, making enrollment less dependent on a separate effort by the mayor's welfare administration. We study the complementary margin. In our setting, converting expanded federal authorization into realized enrollment requires municipal welfare staff to identify, locate, and register eligible families. The designs also draw variation from different parts of the municipal distribution. Frey's threshold design is concentrated among small, low-development municipalities near a funding threshold, whereas the quota reform created more room for expansion in larger municipalities that had not yet absorbed earlier increases. Within his sample, coverage growth through a federally structured outreach channel reduces incumbency advantage and shifts the composition of challengers toward less clientelistic parties. Within ours, coverage growth through a locally managed registration channel produces positive returns for the incumbent.

Second, we contribute to the literature on political accountability under shared governance. A central question in this literature is whether voters can attribute responsibility when multiple levels of government jointly produce policy outcomes (Przeworski et al., 1999; Besley, 2006). Ferraz and Finan (2008) show that voters punish corrupt mayors when randomly assigned audits reveal misuse of federal funds, especially where local media facilitate information transmission. Avis et al. (2018) show that audits also reduce corruption through a legal disciplining channel. Our setting differs because the relevant outcome is positive delivery rather than malfeasance. The results are consistent with voters giving local incumbents some credit for the expansion of a federally funded program when access still depends on municipal action. We do not observe voters' beliefs directly, but the pattern fits an attribution channel in a setting of shared responsibility.

Third, we contribute to the literature on state capacity and the bureaucratic foundations of policy delivery. Besley and Persson (2009, 2011) establish state capacity as a precondition for credible policy delivery, and Finan et al. (2017) survey the personnel and bureaucratic infrastructure through which public programs are implemented. Our findings show that the capacity to expand beneficiary enrollment and the capacity to make that expansion electorally valuable need not coincide. Municipalities with and without a pre-existing CRAS both enrolled more beneficiaries when federal authorization increased, while the estimated electoral return is clearer where a welfare center was already present. Existing offices may therefore matter for how families encounter the local administration as they gain access, beyond the number of families who ulti-

mately receive a benefit.

The remainder of the paper proceeds as follows. Section 2 describes *Bolsa Família*, municipal registration, the quota reform, and the data. Section 3 presents the reform's effects on registration, beneficiary enrollment, and electoral outcomes. Section 4 examines how local welfare institutions shape these responses. Section 5 concludes.

2 Institutional Background and Data

2.1 *Bolsa Família* Program

Program Design. Introduced in 2004, *Bolsa Família* brought earlier federal transfers, including *Bolsa Escola* and *Bolsa Alimentação*, into a single program. Its monthly payment combined a basic benefit for families in extreme poverty with variable benefits tied to the number and ages of children, while families with relevant members were expected to meet health and education conditions. Benefit values and income thresholds changed over time: by September 2009, families with monthly per capita income at or below R$70 qualified for the basic benefit and, depending on their composition, variable benefits; those above R$70 and at or below R$140 qualified for variable benefits. Table 1 traces these thresholds and benefit amounts from the program's introduction onward.

The program's rules and payments are federal, but access depends on municipal registration in *Cadastro Único* (CadÚnico), the national registry used to identify potential beneficiaries. The *Ministério do Desenvolvimento Social* (MDS) sets eligibility criteria and benefit values and selects families using registry information, while *Caixa Econômica Federal* pays recipients directly. By identifying families and collecting their information, municipal administrations become part of the path to a federal benefit, creating an electoral opportunity for mayors through their role in helping families gain access.

The registry records low-income families for *Bolsa Família* and other social programs. From February 2009, it covered families with per capita income below half the minimum wage (R$232.50), a broader group than those meeting *Bolsa Família*'s income thresholds.[5] Registration was thus required for selection but did not guarantee payment: the registry included substantially more families than the program served. Under Decree No. 6,135/2007, the ministry defined and supervised the registry, while

[5] Provisional Measure No. 456/2009 set the monthly minimum wage at R$465 from February 1, 2009.

participating municipalities collected family information using a standardized form.

Federal Rules and Local Responsibility. Municipal governments carried out the local work: they organized registration, coordinated the agencies involved, monitored compliance with program conditions, and maintained the information on which federal selection depended. State governments supported this work by coordinating social assistance, education, and health within their jurisdictions and providing technical assistance to municipalities; they did not set eligibility or benefit values, select beneficiaries, or make payments. Those decisions remained federal responsibilities.[6]

These responsibilities gave mayors influence over access without control over the transfer itself. They could not change eligibility thresholds or benefit values, redirect payments, or guarantee that a registered family would receive a benefit; they could decide how actively staff sought unregistered families, how quickly interviews and updates were completed, and how municipal agencies coordinated their work. Those choices shaped how readily eligible families became visible to the federal system and how municipalities used newly authorized capacity. Our analysis centers on the local implementation margin within federal benefit rules.

Municipal Registration. Registration turned the information families supplied into the record used for federal selection. It required a face-to-face interview about household composition, housing, employment, and income, either at a municipal registration post or with a team visiting a neighborhood or rural community.[7] Municipal staff had the responsibility to locate families, conduct interviews, update records, and coordinate referrals. Once registered, a family meeting the program's criteria could be selected when federal authorization allowed, although registration alone did not ensure immediate benefit receipt: newly available places could go to families already in the registry, while a newly registered family could remain there for a later selection. Registration and beneficiary enrollment thus capture different stages of access.

The *Centro de Referência de Assistência Social* (CRAS) is a major local welfare office through which families could encounter municipal assistance during registration. As the territorial gateway to the *Sistema Único de Assistência Social* (SUAS), it receives families, identifies their needs, and connects them with other services.[8] A welfare office

[6]The division of responsibilities during the study period was governed principally by Law No. 10,836/2004, Decree No. 5,209/2004, and MDS Ordinance No. 246/2005.

[7]See MDS Ordinance No. 376/2008, Decree No. 6,135/2007, and the MDS *Manual do Entrevistador* (2009).

[8]See MDS, *Orientações Técnicas: Centro de Referência de Assistência Social—CRAS* (2009).

could conduct registration interviews, while dedicated registration posts and visiting teams offered other routes into the registry. Through the *Programa de Atenção Integral à Família* (PAIF), these offices could also maintain contact with families beyond registration. Families connected to a local welfare office could thus encounter municipal assistance both while seeking a benefit and through continuing welfare support. This distinction lets us ask whether an existing welfare interface changes the political return to expansion even where enrollment can grow without one.

2.2 Institutional Details of the Quota Reform

Quotas and Enrollment. Municipal quotas set the number of *Bolsa Família* families authorized to receive the benefits in each municipality. The federal government based them on estimates of local poverty, revised periodically as new demographic and income information became available. A higher quota creates room for more families to receive benefits, but actual enrollment also requires eligible families to appear in *Cadastro Único* and be selected for payment. Figure 1 shows that the number of potentially eligible registered families fell below the authorized quota in some municipalities. Figure 2 shows that realized enrollment generally remained near authorized capacity, moving modestly above or below the quota from month to month, while the 2009 expansion temporarily widened the gap. The quota was therefore a nominal ceiling for authorization rather than a binding cap on monthly enrollment.

Priority and Local Effort. Federal selection gave priority to municipalities with lower coverage relative to their estimated poor population, making the stock of eligible registrations consequential for filling authorized capacity. The MDS also monitored whether municipalities had enough registered families to meet their coverage estimates: in 2010, it instructed those with insufficient records to find and register additional families and update existing records.[9] Municipal work could therefore determine how quickly an increase in authorization became benefit receipt, even though selection and payment remained federal responsibilities.

Quota Reform. Before 2009, the federal government allocated municipal *Bolsa Família* quotas using estimates of the number of poor families in the 2000 Census, adjusted for

[9]See MDS Ordinance No. 341/2008 and MDS, *Bolsa Família Informa* No. 215, April 22, 2010. The bulletin reports that insufficient eligible registrations prevented some municipalities from reaching their planned beneficiary counts and directs them to identify and register families and update existing records.

subsequent population growth. The 2009 reform replaced those projections with estimates that accounted for income volatility among families near the eligibility threshold: a family whose income moved above and below that threshold could need support even if a survey did not record it as poor at a particular moment (Gerard et al., 2026). This changed the estimated number of families to be served in each municipality and, consequently, the distribution of authorized capacity across the country.

The revised estimates did not mechanically reduce the number of existing beneficiaries where a municipality's new quota fell below its current coverage: the quota update itself did not force those families out of the program, though it made new allocations less likely in those municipalities.[10] In municipalities whose revised estimates called for greater coverage, the reform created additional capacity that could be filled by eligible families already in *Cadastro Único* or by families whom municipal staff subsequently identified and registered.

The revised national estimate of potential beneficiaries rose from 11.1 million to 12.9 million families.[11] The MDS then phased in the expansion through three rounds of new benefit grants in May, August, and October 2009, bringing 1.3 million additional families onto the payment rolls; it planned to include another 600,000 in 2010.[12]

Quota Update. The federal government updated municipal estimates again before the 2012 election. It had announced a national coverage target of 13.8 million families in 2011; after the sample from the 2010 Census became available in April 2012, the MDS distributed that target across municipalities and announced the new estimates in May. The estimates continued to incorporate the income-volatility adjustment introduced in 2009, now using the more recent Census information to determine where the families to be served were located.[13]

2.3 Data

Our empirical analysis combines five sources of data: administrative records on *Bolsa Família*, family-level records from the *Cadastro Único*, electoral returns, census and

[10] Gerard et al. (2026) document that the 2009 quota update did not force existing beneficiaries to leave the program in municipalities whose quotas fell. This describes the treatment of the quota update; benefit continuation remained subject to the program's ordinary eligibility and administrative rules.

[11] MDS, *Bolsa Família Informa* No. 169, April 30, 2009. This is the national coverage estimate, not a count of benefits paid or the net change in municipal quotas.

[12] MDS, *Bolsa Família Informa* No. 191, October 8, 2009. The bulletin distinguishes the 1.3 million families included in 2009 from the further 600,000 planned for 2010.

[13] MDS, *Informe Bolsa Família* No. 318, May 17, 2012.

household-survey data, and administrative records on local social-assistance infrastructure.

***Bolsa Família* Administrative Records.** We begin with monthly administrative records from the *Ministério do Desenvolvimento Social* on *Bolsa Família* quotas, realized coverage, and total transfers from 2006 to 2012. These data span the pre-reform baseline, the 2009 reallocation, and the post-reform expansion window through the 2012 election, and allow us to measure both authorized and realized program expansion.

***Cadastro Único*.** We also use family-level records from the 2012 *Cadastro Único*, provided by the *Ministério do Desenvolvimento Social*. The file covers families recorded in the registry in 2012, including those registered in earlier years. It reports their municipality of residence, per-capita family income, family characteristics, and dates of first registration and last update. The first-registration date identifies entry into the registry separately from subsequent updates and lets us construct registration cohorts, including families first registered before the reform. We use income recorded in the 2012 snapshot to distinguish families with a potential *Bolsa Família* income profile from other registered families.[14]

Electoral Records. We then use electoral records from the *Tribunal Superior Eleitoral* (TSE) for the 2008 and 2012 municipal elections. These records provide candidate-level vote totals and characteristics, including education, prior occupation, and party affiliation, as well as municipal election turnout.

Census and Household Surveys. We combine the 2000 Census from the *Instituto Brasileiro de Geografia e Estatística* (IBGE) with poverty estimates from the 2006 *Pesquisa Nacional por Amostra de Domicílios* (PNAD). The Census supplies the municipal distribution of poverty, while the PNAD supplies state-level poverty totals; together with pre-reform population-growth estimates, these inputs let us reconstruct how municipal quotas would have been allocated using the information and rule available before the 2009 change. We assess the reconstructed rule against official pre-reform quota assignments before using it to estimate the allocation that would have prevailed without

[14] During the study period, registry information required updating or revalidation every two years under Decree No. 6,135/2007. Income recorded in the 2012 file may therefore differ from income at first registration. The cohort exercise covers families present in that snapshot; it does not recover the earlier income of those families or families no longer recorded there.

the 2009 change. Census measures also provide predetermined municipal characteristics for the analysis.

Censo SUAS. Finally, we use annual *Censo SUAS* records on CRAS units from 2008 through 2012, with the 2007 wave used where needed to date earlier openings. The 2008 wave describes the local welfare infrastructure in place before the quota reform, including whether an office reported active outreach and its reported count of *Bolsa Família* families served. Later waves describe the opening and expansion of the office network during the mayoral term.

2.4 Sample Construction

Municipal Panel and Data Availability. We start with 5,568 municipalities in the integrated election data, observed in both 2008 and 2012. We link them to the administrative *Bolsa Família* records by municipal identifier; 63 lack the quota or enrollment measures required for the analysis, leaving 5,505 municipalities. These gaps reflect missing measures in the linked data, not an absence of *Bolsa Família* from the municipality.

Electoral Sample and Record Quality. We follow the mayor elected in 2008 and measure that mayor's vote share in each election. Among municipalities with complete program measures, 2,365 had a 2008 winner who ran again in 2012. We retain contested elections, with more than one candidate in the decisive round, and require usable vote records, an unambiguous candidate match, and consistent election records in both years. These restrictions leave 2,105 municipalities for the electoral comparison of incumbents who sought another term.

Estimation Sample. The remaining common-specification requirements exclude 24 municipalities with missing municipal-level information and 3 with missing mayor characteristics. The final estimation sample contains 2,078 municipalities and 4,156 municipality-year observations, used across the main specifications. For comparison, we separately construct a descriptive sample of 4,976 municipalities with complete core program measures and municipal characteristics, a positive population denominator, and usable elections in both years, without requiring the 2008 mayor to run again in 2012. Table 2 compares program measures and municipal, electoral, and mayor characteristics across the two samples.

Selection. Because the electoral sample includes only mayors who ran again in 2012, we examine whether the quota shock is related to their decision to rerun. In a separate universe of municipalities constructed before that restriction, the shock has no clear association with rerunning, and reweighting by estimated rerunning probabilities preserves a positive vote-share response. We also examine a different form of selection: whether unobserved municipal characteristics could account for the electoral reduced form within the estimation sample. A coefficient-stability exercise following Oster (2019) finds that, under the recommended benchmark, unobserved selection would need to be 2.79 times as strong as selection on the included observables to overturn that estimate.

2.5 Descriptive Statistics

Census Information. Panel A of Table 2 compares predetermined municipal characteristics across the descriptive and estimation samples. Their average urban shares, poverty rates, per-capita incomes, and inequality measures are similar. Median population is just over 10,000 residents in both samples, although municipality size ranges from fewer than 1,000 residents to several million.

***Bolsa Família* Program Information.** Panel B describes authorized quotas and realized enrollment before the reform and their changes through 2012. Municipalities in the estimation sample had an average of 879.87 beneficiary families per 10,000 residents in 2008; realized coverage rose by 203.50 on average, with a median increase of 163.15. The realized measures use twelve-month averages of monthly beneficiary-family counts, and the rates use fixed 2006 population so that the reported changes reflect enrollment rather than changes in the denominator.

Election Information. Panel C compares the municipal races and the 2008 winners tracked in the electoral analysis. The average number of candidates is similar across samples in both elections, while the 2008 winner's vote share averages 54.97 percent in the descriptive sample and 52.92 percent in the estimation sample. A 2012 vote share for that same mayor is observed only where the mayor ran again.

Mayor Characteristics. Panel D describes the mayors elected in 2008. Their average age is lower in the estimation sample, and the distribution of prior occupations differs,

especially for public-sector and business occupations. These differences help characterize the incumbent candidates whose electoral outcomes enter the analysis.

3 Impact of the 2009 *Bolsa Família* Reform

Can mayors gain electoral support from expanding a federal transfer program when their administrations find and register eligible families? Federal policy determines how many families may receive benefits and sets transfer amounts, while municipal staff help turn authorization into access. We compare municipalities with different increases in authorized capacity and trace the resulting changes in registration and enrollment. We then use the formula-driven increase in authorization as an instrument to estimate the electoral return to quota-induced beneficiary expansion.

3.1 Policy-Induced Variation in Authorization and Coverage

Authorization. Federal authorization can expand *Bolsa Família* only if eligible families are registered in *Cadastro Único*. In 2009, the Ministry of Social Development revised the municipal quota formula and later updated quotas using the 2010 Census. We measure each municipality's increase in authorization as its official 2012 quota minus the quota implied by the earlier allocation rule. Figure 1 shows that roughly one-third of municipalities had fewer potentially eligible registrations than authorized slots in 2008, leaving room to register new families. Figure 2 shows the gap between authorized quotas and beneficiary enrollment after the reform. Figure 3 compares unused authorization under the official and counterfactual quotas.

Registrations. Larger quotas were accompanied by more first registrations in *Cadastro Único*, consistent with municipalities seeking families to fill new slots. A one-standard-deviation increase in authorization is associated with 48.47 additional registrations per 10,000 residents, concentrated among families reporting income at or below R$140 per capita in 2012 (Table 3). Figure 4 shows the size and income composition of cumulative first-registration cohorts among families present in the 2012 registry.

Realized Enrollment. Authorization created room for more families to receive *Bolsa Família*, and registrations brought more families into the program's records. The next question is whether these steps increased the number of families actually receiving

benefits. Comparing the twelve-month average number of beneficiary families in 2008 and 2012, a one-standard-deviation increase in authorization induced 62.14 additional beneficiary families per 10,000 residents (Table 4). Newly authorized slots could be filled by families already registered or by those registered during the mayoral term, so the registration and enrollment results describe related stages of access without identifying the same households. Figure 5 shows how quotas and enrollment changed over the term.

3.2 Identification Strategy

Mayors seeking electoral support may have incentives to increase both registrations and realized enrollment. We therefore compare changes in electoral outcomes from 2008 to 2012 across municipalities exposed to different increases in federal authorization following the 2009 quota reform and its 2012 update. In a two-period difference-in-differences design, we use the federal authorization shock as an instrument for beneficiary expansion, isolating the component of enrollment induced by the increase in authorized capacity. Formally, we estimate

$$\Delta \mathrm{B}_{\mathrm{m}} = \pi_0 + \pi_1 \mathrm{Z}_{\mathrm{m}} + \mathbf{X}'_{\mathrm{m},0}\boldsymbol{\pi} + \eta_{\mathrm{m}}, \tag{1}$$

$$\Delta \mathrm{Y}_{\mathrm{m}} = \beta_0 + \beta_1 \widehat{\Delta \mathrm{B}}_{\mathrm{m}} + \mathbf{X}'_{\mathrm{m},0}\boldsymbol{\beta} + \varepsilon_{\mathrm{m}}, \tag{2}$$

where $\Delta \mathrm{Y}_{\mathrm{m}}$ is the 2008–2012 change in an electoral outcome for municipality m. The variable $\Delta \mathrm{B}_{\mathrm{m}}$ is the change in beneficiary families over the same period. The instrument Z_{m} measures the increase in authorized quotas relative to the pre-reform allocation rule. The vector $\mathbf{X}_{\mathrm{m},0}$ contains the full set of predetermined controls used in each specification. The first equation relates authorization to realized enrollment; the second estimates the electoral effect of that federally induced enrollment.

Counterfactual Quotas. We construct the counterfactual quota by applying the pre-reform allocation rule to information available before the reform, following Gerard et al. (2026):

$$\mathrm{CounterfactualQuota}_{\mathrm{m}}^{2009} = \frac{\mathrm{Poor}_{\mathrm{m}}^{2000}\,\mathrm{Growth}_{\mathrm{m}}^{2000,\,2006}}{\sum_{\mathrm{k}\in\mathrm{s}} \mathrm{Poor}_{\mathrm{k}}^{2000}\,\mathrm{Growth}_{\mathrm{k}}^{2000,\,2006}} \times \mathrm{Poor}_{\mathrm{s}}^{2006} \times 1.18, \tag{3}$$

where $\mathrm{Poor}_{\mathrm{m}}^{2000}$ is the number of poor families in municipality m in the 2000 Census, $\mathrm{Growth}_{\mathrm{m}}^{2000,\,2006}$ is its estimated population growth factor through 2006, and $\mathrm{Poor}_{\mathrm{s}}^{2006}$ is the 2006 PNAD survey estimate of poor families in state s, which contains municipal-

ity m. The factor 1.18 incorporates the nationwide increase in authorized slots that accompanied the 2009 revision.

Instrument. We then define the instrument as

$$Z_m = \frac{\text{OfficialQuota}_m^{2012} - \text{CounterfactualQuota}_m^{2009}}{\text{Population}_m^{2006}} \times 10{,}000, \tag{4}$$

where $\text{OfficialQuota}_m^{2012}$ is the quota assigned to municipality m before the 2012 election, and $\text{Population}_m^{2006}$ is the population estimate available before the 2008 election.

Our instrument extends the comparison in Gerard et al. (2026) from 2009 to 2012 to capture the authorization available over the mayor's full term. Following their application of the recentering logic in Borusyak and Hull (2023), we subtract the quota implied by the pre-reform rule from the official quota. This removes the allocation the municipality would have received under the old rule, leaving the additional authorization generated by the federal changes. We treat this cumulative change as plausibly exogenous to the mayor elected in 2008: the federal government changed the quota allocation formula in 2009 and updated municipal quotas in 2012, and the municipality's eventual allocation was neither chosen by the mayor nor known at that election.

Validity of the Design. For the electoral comparison to identify an effect, municipalities receiving different shocks must have followed comparable electoral trends in the absence of the expansion, conditional on predetermined characteristics. The instrumental-variable interpretation further requires that authorization affect electoral outcomes only through beneficiary growth and that higher authorization not induce lower enrollment. The federal allocation rule provides variation in authorization that individual mayors did not choose, while the checks below assess whether this variation supports an electoral interpretation under the design's identifying assumptions.

3.3 Electoral Responses

In this section, we estimate the causal effects of the *Bolsa Família* expansion on a set of electoral outcomes. We show that quota-induced beneficiary growth increased the vote share of mayors seeking reelection, while the evidence does not establish effects on their probability of winning or on turnout. The positive mayoral return contrasts with the negative local-incumbency response in Frey (2019) and echoes the finding in Labonne (2013) that local incumbents gained votes where a conditional cash transfer

reached more communities. Taken together, the results are consistent with municipal involvement in delivering a federal benefit creating an opportunity for mayors to gain electoral support.

Authorization. Table 5 shows the reduced-form effects of expanded authorization on electoral outcomes. Because an authorized slot need not be filled, this comparison captures the electoral response to the quota increase whether or not families subsequently received benefits. Where quotas expanded more, incumbents gained vote share, with limited evidence of lower turnout and no clear effect on winning conditional on rerunning. Together, these outcomes point to a gain in vote share without a demonstrated gain in reelection or voter participation. They leave open whether voters switched candidates, opposing voters stayed home, or both.

Registrations. Table 6 scales the same electoral response by new registrations in the *Cadastro Único*, a measure of quota-induced expansion. The positive vote-share pattern appears for families reporting income at or below the potential-eligibility threshold, while winning and turnout show no clear pattern. The first stage is weak for registrations above the R$140 per capita threshold, so the corresponding scaled estimates are weakly identified. These comparisons cannot separate a response to new registration from subsequent benefit receipt, since expanded quotas could also reach families already in the registry.

Realized Enrollment. Registrations show that municipalities reached more families, but registration alone does not provide a *Bolsa Família* benefit; as Section 3.1 shows, expanded authorization also increased realized enrollment, meaning that additional families began receiving transfers rather than merely being registered. We ask whether this expansion in benefit receipt brought electoral returns. In the preferred specification, a one-standard-deviation increase in quota-induced enrollment raises incumbent vote share by 3.08 percentage points (Table 7), while the estimates do not establish a corresponding gain in winning conditional on rerunning or a change in turnout. The enrollment measure includes both families newly registered during the mayoral term and families already in *Cadastro Único*; the estimates cannot separate their contributions.

The electoral accounting helps interpret where the vote-share gain appears: Table 8 shows an increase in incumbent votes alongside a decline in votes for other candidates. This pattern is consistent with voters shifting support toward the incumbent,

although aggregate outcomes cannot identify how individual voters changed their behavior. Because municipal staff could help families obtain a federally funded transfer, the increase in benefit receipt offers a possible link between local assistance and the incumbent's electoral gain.

3.4 What Expanded Access Means for Families

The electoral return accompanies expanded access to a program that can improve families' living conditions. For families who receive *Bolsa Família*, the transfer adds income and is linked to health and education conditions. Existing research helps explain why that access could matter to households.

Health. Rasella et al. (2013) find that greater *Bolsa Família* coverage is associated with lower childhood mortality in Brazilian municipalities, particularly from poverty-related causes. Using linked records for children in poor families, Ramos et al. (2021) also find lower mortality among program beneficiaries. Together, the studies connect access to the transfer with a health outcome of immediate importance to families, while examining different populations and measures of program exposure.

Education. School attendance is a condition of *Bolsa Família* for families with children, so access to the transfer can also help keep children in school. Using school census data, Glewwe and Kassouf (2012) find that the introduction of *Bolsa Escola*/*Bolsa Família* increased enrollment and grade promotion while reducing dropout rates. In a household panel, de Brauw et al. (2015) find gains in school participation and grade progression concentrated among girls, particularly in rural areas and among older girls in urban areas. These findings describe a benefit that can extend beyond the income received during childhood.

Income and Poverty. The transfer adds directly to household resources. Using household surveys, Ferreira de Souza et al. (2019) compare income distributions with and without *Bolsa Família* payments and find reductions in measured poverty and inequality, particularly extreme poverty. Looking at a more immediate household margin, Martins and Monteiro (2016) find greater food purchases and food availability among low-income beneficiary families than among comparable nonbeneficiaries. The two studies show how receipt can matter both for a family's income position and for what it can bring home.

Electoral Returns and Local Implementation. Electoral incentives can also shape what families receive from a decentralized program. Studying *Bolsa Escola*, de Janvry et al. (2012) find larger reductions in school dropout where mayors could seek reelection; those mayors adopted more transparent implementation practices associated with better program performance. Frey (2019) finds a different political consequence of *Bolsa Família* expansion: lower incumbent advantage, more electoral competition, and less support for clientelistic parties. He interprets these changes as consistent with transfers reducing poor voters' dependence on local political intermediaries, a potential gain for families beyond the payment itself.

3.5 Robustness

We assess the vote-share result under alternative comparisons and outcome definitions, including checks for selection into the electoral sample. The estimate remains positive under several changes to measurement, weighting, and extreme observations, but weakens when the design accounts differently for baseline municipal characteristics. These checks show where the preferred comparison has empirical support and where it is sensitive.

Control Variables. Both main specifications account for the incumbent's party and the *Partido dos Trabalhadores* (PT) vote share in the previous presidential election, as well as the pre-reform quota, beneficiary coverage, and average benefit value. The preferred specification also accounts for municipality size, urbanization, inequality, illiteracy, and federal municipal transfers, together with the mayor's age, gender, education, marital status, and occupation. Tables 9, 10, and 11 add these groups separately, build them up, and remove them from the preferred specification. The vote-share response remains positive, though its size depends on how we account for pre-reform municipal differences.

Political Strength and Other Channels. Political strength may shape how many families a municipality actually enrolls. Incumbents' 2008 vote share predicts subsequent realized expansion but not the federal authorization shock (Table 12); this difference motivates using authorization to isolate beneficiary growth from local political strength. Authorization could also affect municipal resources or benefit amounts: the shock is associated with changes in *Fundo de Participação dos Municípios* (FPM) transfers and, less clearly, average benefit value (Table 13). The preferred specification controls for pre-

reform transfers and benefit values, helping account for existing differences between municipalities, but it cannot rule out electoral effects from changes in either one after authorization expanded.

The program's association with the PT also makes the mayor's party a natural place to look for differences in electoral returns. Table 14 shows a positive estimate for non-PT mayors and an inconclusive estimate for PT mayors, but the direct comparison does not establish a difference between them. The data therefore do not show a clear partisan pattern in the local return or how voters assigned credit between federal and municipal politicians.

Balance and Selection. Municipalities receiving larger quota increases might already have favored their incumbents, or the expansion might have affected which mayors ran again. We find no clear evidence of either pattern: the quota shock is not clearly associated with the incumbent's 2008 vote share or with the decision to rerun in 2012 (Tables 15 and 16). Reweighting by the estimated probability of rerunning also preserves the vote-share result (Table 17). Together, these checks lessen concerns about baseline political strength and selection into the electoral sample, though they cannot establish how support would have changed without the reform.

Alternative Definitions. Table 17 asks whether the vote-share result depends on extreme observations, the electoral denominator, the timing of authorization and enrollment, the weight given to mayors who reran, or whether expansion is measured relative to residents or families. The response remains positive when we limit extreme vote changes or quota shocks, use registered voters as the denominator, reweight for rerunning, or scale by families. The 2009 column instead pairs authorization and realized enrollment growth through 2009 while retaining the 2012 electoral outcome; its vote-share estimate is imprecise but remains positive. Table 18 further shows a positive response when authorization moves municipalities above beneficiary-growth thresholds, without identifying a separate effect of crossing a particular threshold.

Municipality Size and Region. Municipality size is relevant to the reform: the *Ministério do Desenvolvimento Social* (MDS) described the 2009 expansion as prioritizing metropolitan areas to reach poor families still outside the program.[15] The positive vote-share response is visible among larger municipalities, including the upper population

[15]MDS, *Bolsa Família Informa* no. 191, October 8, 2009. The bulletin also reports that the Northeast received the largest number of new beneficiary families in the expansion.

tail, while estimates for smaller municipalities are inconclusive (Table 19); Figures 6, 7, and 8 put this size comparison in context by showing the wide distribution of municipal population, beneficiary-family stocks, and authorized quotas, with population weights giving larger municipalities more influence over the pooled estimate. Since the 2009 expansion reached every region and added the most families in the Northeast, we also compare that region with the rest of the country; Table 14 does not establish a difference in their electoral returns.

Baseline Coverage and Prior Expansion. Our positive mayoral return contrasts with the negative local-incumbency response in Frey (2019), whose design centers on small, low-HDI municipalities. To see whether the samples point to different electoral responses, Table 20 separates our municipalities using a close approximation to the thresholds in his design: fewer than 30,000 residents and an HDI below 0.7, both measured in 2000.[16] In our sample, this restriction also selects municipalities with higher *Bolsa Família* enrollment before the reform. We therefore also compare municipalities separately by their 2008 beneficiary coverage.

Authorization increased realized enrollment on both sides of the Frey-like sample split, with a stronger first stage inside it. Yet the positive vote-share return appears outside that group and among municipalities with lower baseline coverage; the estimates inside the group and above the coverage median are inconclusive. One possible interpretation is that earlier exposure to the program made another enrollment increase less politically salient, even where it still reached more families. These comparisons cannot establish political saturation: baseline coverage differs along with other municipal characteristics, and Frey's health-financing design changes the route through which families enter the program.

4 Mechanisms

Our positive mayoral return contrasts with the finding in Frey (2019) that *Bolsa Família* expansion reduced support for local incumbents. How families encounter the program may help explain the difference: the federal government pays the transfer, while municipal staff can help families gain access. Authorization raises enrollment both with and without a pre-reform *Centro de Referência de Assistência Social* (CRAS), while the estimated electoral return is concentrated where a center was already present. Within that

[16] Frey's funding rule used the 2000 Census HDI and official 2003 population estimates. Our comparison uses the available 2000 municipal population, so it is an approximation to his eligibility group.

group, returns are larger where staff report active outreach and serve more beneficiary families. These comparisons motivate local contact as a possible source of political credit.

Families may first encounter the program at a municipal office or through an outreach team. Staff can identify them, explain eligibility, collect information, and direct them to other services. This contact may make the municipality's role visible even though benefit values and payments are federal. We first consider other ways that expanded access could affect local elections.

4.1 Alternative Mechanisms

Material Benefits and Political Credit. Receiving the transfer can change political support even when a family has little contact with municipal staff. In Uruguay, Manacorda et al. (2011) find that an antipoverty transfer increased support for the government that provided it, with effects persisting after payments ended. Their setting shows how income and beliefs about government can matter politically. In Brazil, families may associate the payment with federal policy, local help in obtaining it, or both; their spending may also reach other residents through local commerce.

Other Registry-Linked Programs and Fiscal Channels. For families, registration in *Cadastro Único* could open access to programs beyond *Bolsa Família*, including the social electricity tariff.[17] Help with registration may therefore be valuable even when it does not lead to a transfer. A separate possibility is that expanded authorization coincided with changes in municipal resources or benefit amounts. Table 13 examines the changes in FPM transfers and per-family benefit values visible in our records; it cannot capture every benefit connected to registration.

Complementary Services and Political Relationships. Municipal welfare offices offer services beyond registration. Before the reform, the *Programa de Atenção Integral à Família* (PAIF) provided family support and referrals through CRAS. Families could value this assistance separately from the transfer, and it may also change their relationships with local politicians. Survey and focus-group evidence in Sugiyama and Hunter (2013) suggests that beneficiaries did not regard *Bolsa Família* as contingent on

[17] Law No. 12,212/2010 linked eligibility for the social electricity tariff to registration in *Cadastro Único* under its income criteria. This establishes a potential route, not a measured response of tariff receipt to the quota shock.

their votes, while Frey (2019) interprets reduced incumbent advantage as consistent with poorer voters becoming less dependent on clientelistic exchange. These studies leave room for political responses that do not arise from credit for a particular office visit.

4.2 Local Welfare Offices and Electoral Returns

Registration is a point at which families may encounter municipal assistance. A social welfare center gives them a place to seek help, meet municipal staff, and access social programs. We ask whether the same federal expansion brings different electoral returns where this point of contact was already available. In our sample, 1,394 municipalities had a recorded center before the reform and 684 did not.

Authorization increased beneficiary enrollment both where a social welfare center was already present and where none was recorded, with no clear difference between the enrollment responses. In Table 21, the estimated mayoral vote-share gain appears in municipalities with a center before the 2008 election. These municipalities also differed in population, poverty, and earlier program coverage (Table 22), and reweighting to balance observed pre-reform characteristics attenuates the electoral contrast; the comparison therefore describes where the gain appears. An existing center could make municipal help with program access more visible, even though the federal government pays the benefit.

Active Outreach and Family Contact. An office need not wait for families to come to it: through active outreach, staff can seek out households that have not asked for help, explain eligibility, and assist them in accessing the program. This contact may make the municipality's role visible to families who otherwise would have little reason to visit a welfare center. Among municipalities that already had a CRAS before the reform, we compare those that reported active outreach with those that did not.

Table 23 shows a larger enrollment response where centers did not report active outreach, but a larger estimated electoral return where they did. The difference in electoral returns is imprecise, yet the opposing patterns suggest that beneficiary counts alone may not explain where mayors gained votes. Outreach was already in place before the reform, and centers and the families they served may differ in other ways. Contact offers one explanation for why municipal effort became more visible as families gained access.

Family Follow-Up. *Programa de Atenção Integral à Família* (PAIF) assists families facing social vulnerability and helps them access benefits and public services.[18] Follow-up may keep families in contact with municipal staff after registration, making the municipality's role in helping them navigate the program more visible. We measure this activity using the pre-reform number of *Bolsa Família* families recorded as served by welfare offices.

Table 24 first compares municipalities with a positive count of beneficiary families served with those without one. The enrollment and electoral responses do not clearly differ between these groups, suggesting that a simple record of any activity may miss differences in the scale of family contact. Among the municipalities with a positive pre-reform count, Table 25 then compares those serving more families with those serving fewer. The evidence supports a larger electoral return in the higher-volume group. This pattern is consistent with more extensive contact with municipal staff helping turn program expansion into electoral support.

Institutional Exposure. The presence of a center is only one part of families' exposure to municipal assistance. An established office may know more local families and have working routines for identifying needs and helping them access services. When a new mayor takes office, that existing structure may make it easier to reach families even if the administration changes senior staff. A newly opened office, in turn, may make municipal action especially visible. We use the official CRAS censuses from 2007 through 2012 to compare centers by their reported opening dates and describe how the network changed during the mayoral term.

Table 26 compares municipalities with older offices, more recently opened offices, and no recorded center before the reform. The electoral response tends to be larger around older offices, but the adjusted comparisons do not establish that the return grows steadily with office age. Table 27 extends the description to offices reported as opening during the mayoral term. Those later openings may reflect municipal decisions made after authorization expanded, and some reported dates may refer to predecessor facilities. The cohorts therefore describe where the response appears rather than the effect of operating a center for longer.

Larger electoral responses tend to appear around centers established before the reform, rather than offices first recorded during the mayoral term. Together, the center,

[18]The Ministry's institutional history of PAIF dates its establishment to 2004. In 2009 it became the *Serviço de Proteção e Atendimento Integral à Família*, retaining the acronym. The original questionnaire label for the family-count item used below is incomplete, so we treat the count as a proxy for reported service activity, not a measure of how often families met staff.

outreach, PAIF, and office-cohort comparisons suggest municipal assistance as one possible link between federal expansion and local electoral support.

5 Conclusion

Federal cash transfers can limit local discretion over benefits while still relying on municipal staff to identify eligible families and help them enter the program. We use a revision of federally assigned enrollment quotas to study whether this local role gives mayors an electoral return from expanding *Bolsa Família*.

Municipalities receiving more authorization registered more families and enrolled more beneficiaries. Among mayors seeking reelection, a one-standard-deviation increase in federally induced enrollment raises incumbent vote share by 3.08 percentage points in our preferred specification. Incumbent votes rise as votes for other candidates fall, showing how the electoral return appears in aggregate vote totals.

Registration was one route through which municipal staff could help families gain access, alongside enrollment of families already in the registry when quotas expanded. Enrollment increased in municipalities with and without a pre-existing social welfare center, while the estimated mayoral vote-share gain was concentrated where a center was already in place. Within that group, estimated returns were larger where staff reported active outreach and where offices served more beneficiary families. These patterns point to municipal assistance as a way families may see the local role in delivering a federal benefit.

For newly enrolled families, access to *Bolsa Família* means additional income that can support their children's health and education, and the possibility of greater security in meeting everyday needs. Municipal assistance with registration can help families reach that benefit, even though the federal government funds and pays it. This local role offers a link between a gain for families and the electoral return for incumbent mayors.

Youth Benefits	–	–	–	2	2	2	2	2	2	2	2	2	2	2	2	2	2	2	2	2

Notes: Columns cover 2004–2018 and report effective months: legal dates for income thresholds and first payment months for benefit changes. Values are nominal BRL; unchanged rules carry forward through December 2018. A dash indicates a component not yet implemented. The basic benefit applies only to extremely poor families. Maximum Benefit is the largest monthly sum of the basic benefit, the capped variable benefits and the separately capped youth benefits for an eligible family with the requisite composition; it is not a universal ceiling on actual transfers. Variable Benefits is the shared family limit for children aged 0–15, pregnancies and nursing children; Youth Benefits has a separate limit of two per family. Pregnancy and nursing benefits pay nine and six monthly installments per eligible episode, respectively. The family-specific extreme-poverty supplement introduced in 2012 and legacy-program compensation are excluded from this display and from Maximum Benefit; subnational supplements are also excluded.

Notes: Each observation is one municipality. Descriptive Sample contains municipalities with a balanced 2008–2012 election panel, core program and Census measures, and common election-quality restrictions, without conditioning on the mayor rerunning; N is the number with nonmissing values in each row. Regression Sample is the exact locked regression sample used in the headline estimates (2,078 municipalities). Permitted families in 2008 are the pre-reform authorized quota (EST 2006); realized families are 12-month averages. Percentage and per-10,000 measures use fixed 2006 population. Every Δ is the corresponding 2012 value minus its 2008 value. Candidate counts describe first-round mayoral candidates. Seeking reelection indicates that the sitting mayor contested the 2012 election. Vote share tracks the 2008 winner: the 2008 value is that winner's baseline share, and the 2012 value and its change are observed only when the same mayor reran. Mayor characteristics describe the 2008 winner and match the headline controls; age squared is omitted because it is a deterministic transformation of age.

Figure 1: Share of Municipalities with Registrations Below Authorized Quotas

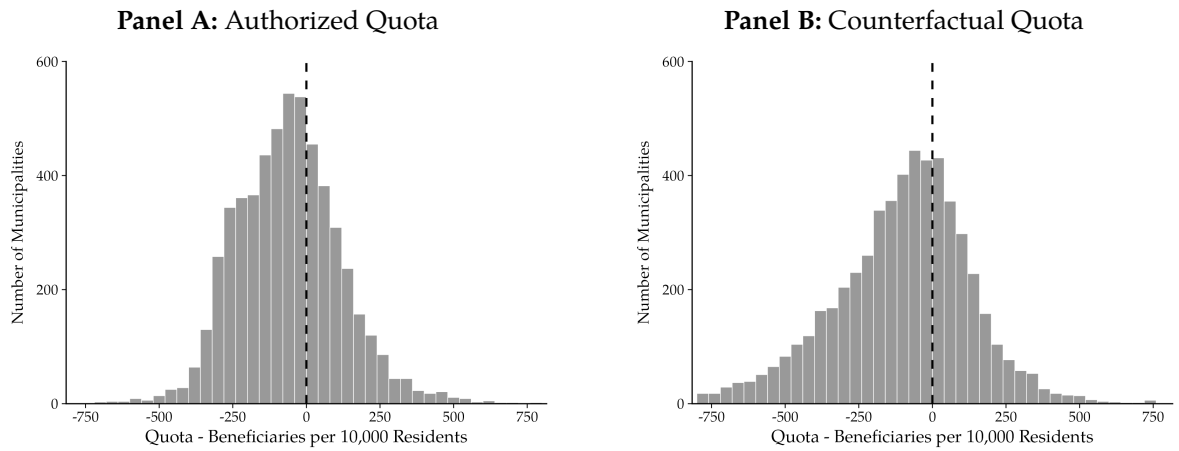

Notes: Each bar is the unweighted share of municipalities with complete registry and quota data in the displayed year where the cumulative number of families in the 2012 *Cadastro Único* snapshot with reported per-capita income at or below R$140 and a first-registration date no later than that year is strictly below the municipality's December authorized *Bolsa Família* quota. The 2008 count includes registrations dated 2008 or earlier. The source aggregate does not separate 2006 or 2007, so the four displayed years are 2008, 2009, 2010, and 2012. Income is measured in 2012, not necessarily at first registration; families who exited the register before the 2012 snapshot are absent. These bars do not measure benefit take-up.

Figure 2: Realized Enrollment as a Share of Authorized Quota

Notes: For each municipality-month, we compute the ratio of realized *Bolsa Família* beneficiaries to the authorized quota. The solid line plots the quota-weighted cross-municipal mean of these municipality-level ratios. The shaded band spans the weighted 25th to 75th percentile. The dashed horizontal line marks full take-up (ratio = 1). Before 2007, municipalities operated well below their authorized ceilings, and the rapid convergence toward 1 reflects the administrative build-up of the program in its first years. After this initial convergence, realized enrollment generally tracked authorized capacity closely. The 2009 reform temporarily broke that alignment: expanded quotas opened a gap between authorized slots and realized beneficiaries, creating the local implementation margin through which municipalities had to identify, register, and enroll additional eligible families.

Figure 3: Distribution of Slack: Authorized Quota vs. Counterfactual Quota

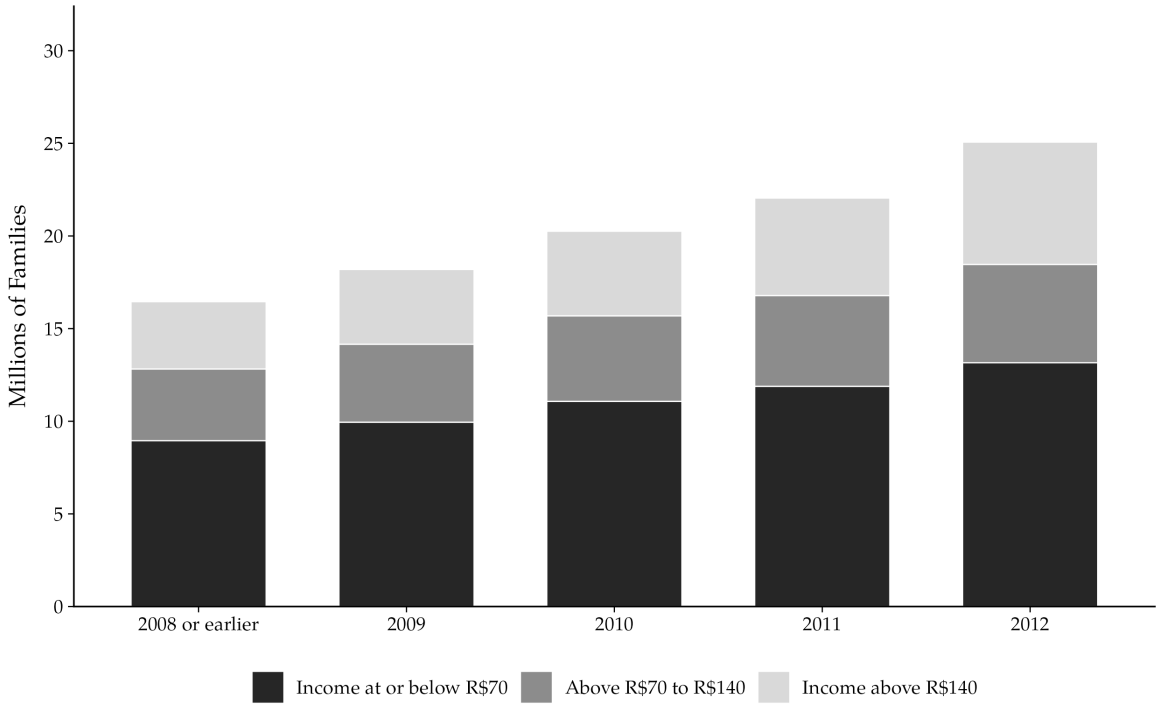

Notes: Each panel shows slack in December 2012 per 10,000 residents using fixed 2006 population. Slack is quota minus the 12-month average stock of beneficiary families in 2012 (not realized enrollment minus quota). Panel A uses the official authorized 2012 quota; Panel B uses the counterfactual 2009 quota implied by the previous allocation rule. Positive values indicate authorized room not translated into realized enrollment, while negative values indicate realized enrollment above the relevant quota. The dashed vertical line marks zero slack. Both panels retain the common display window from -800 to 800 beneficiary families per 10,000 residents to limit the influence of extreme observations.

Table 3: Registration Expansion in *Cadastro Único*

	Δ Registrations in *Cadastro Único*	
	(1)	(2)
Panel A: All registered families		
ΔQuota_m (π_1)	34.464***	48.471***
	(9.096)	(9.465)
Kleibergen–Paap F	14.36	26.22
Panel B: Income above R$140		
ΔQuota_m (π_1)	4.020	4.870
	(3.467)	(3.649)
Kleibergen–Paap F	1.34	1.78
Panel C: Income at or below R$140		
ΔQuota_m (π_1)	30.444***	43.601***
	(7.570)	(8.116)
Kleibergen–Paap F	16.17	28.86
Panel D: Income at or below R$70		
ΔQuota_m (π_1)	24.910***	34.323***
	(6.285)	(7.119)
Kleibergen–Paap F	15.71	23.25
Bolsa Família Characteristics	✓	✓
Party Characteristics	✓	✓
Municipality Characteristics		✓
Mayor Characteristics		✓
Number of Mayors	2,078	2,078
Observations	4,156	4,156

Notes: All columns retain the locked 2008–2012 sample, quota-shock instrument, municipality and year fixed effects, 2006-population weights and state-clustered CRV1 standard errors. Controls are interacted with post. Registration expansion counts families first registered in 2009–2012 and still observed in the 2012 *Cadastro Único* snapshot. Income (monthly per capita) and municipality are measured in 2012. These are surviving entry cohorts, not historical net stocks or verified *Bolsa Família* recipients. The income definitions overlap: the at-or-below-R$140 group combines the two lower-income bands. Each coefficient reports the change in family registrations per 10,000 residents (fixed 2006 population) induced by one weighted SD of the quota shock. Natural-rate first stages add across disjoint income groups. Parentheses report standard errors. Stars use null-imposed state wild-cluster bootstrap p-values from 9,999 draws: $*\ p < 0.10$, $**\ p < 0.05$, $***\ p < 0.01$.

Figure 4: Family Registrations in the 2012 *Cadastro Único* Snapshot by Reported Income

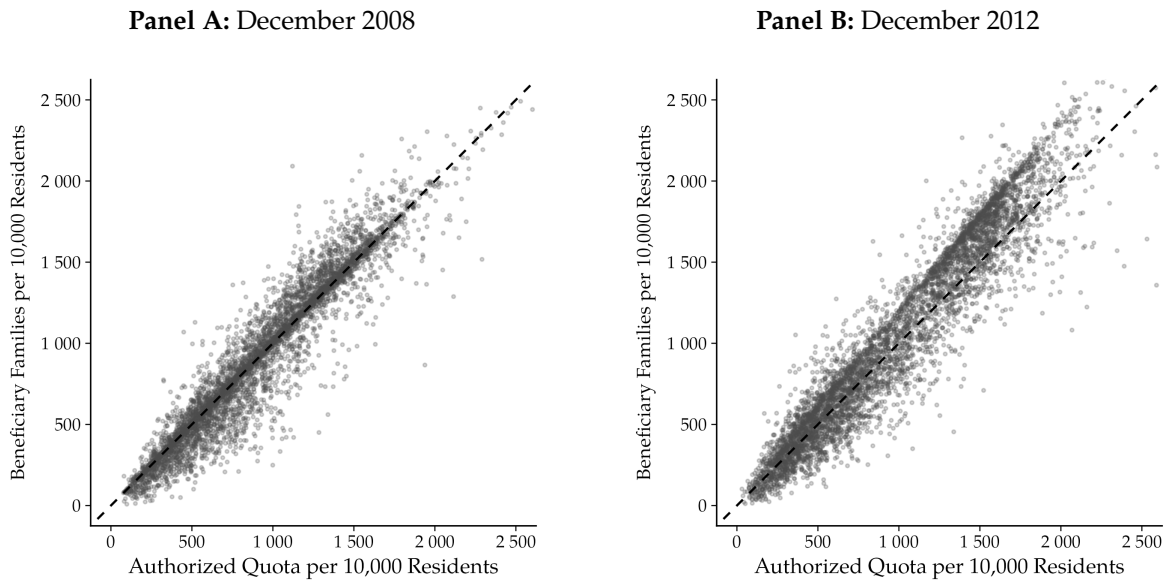

Notes: The vertical scale is in millions of families. Counts sum municipality-level family records in the 2012 snapshot. "2008 or earlier" pools all valid registration dates through December 2008. Municipality and nominal monthly per-capita family income are recorded in 2012; income is not measured at registration. Registration dates outside 1900–2012 are excluded. Each bar cumulates families through the indicated registration year, conditional on their presence in the 2012 snapshot. Stacked segments are mutually exclusive 2012 income categories: at most R$70, above R$70 through R$140, above R$140, and missing or invalid income. These are retrospective cohorts, not historical registry stocks. The available aggregates pool years through 2008 and contain no registrations after 2012; they cannot support separate 2004–2008 bars or a series through 2016.

Table 4: First-Stage Estimates

	ΔBeneficiaries$_m$	
	(1)	(2)
ΔQuota$_m$ (π_1)	0.252***	0.343***
	(0.051)	(0.053)

Bolsa Família Characteristics	✓	✓
Party Characteristics	✓	✓
Municipality Characteristics		✓
Mayor Characteristics		✓
Number of Mayors	2,078	2,078
Observations	4,156	4,156

Notes: All columns absorb municipality and year effects. All columns use 2006-population weights and state-clustered standard errors. The instrument and endogenous variable are rates per 10,000 residents using fixed 2006 population and are reported per one analysis-weighted SD. Column (1) includes 2008 incumbent party, 2006 PT presidential vote share, baseline 2008 program intensity and per-family benefit value, and log 2006 quota. Column (2) adds municipality and mayor characteristics, including baseline 2008 FPM transfers in the municipality group. Predetermined controls are interacted with post. Standard errors are in parentheses. Stars denote two-sided null-imposed state wild-cluster bootstrap p-values from 9,999 Rademacher draws: $*$ $p < 0.10$, $**$ $p < 0.05$, $***$ $p < 0.01$.

Figure 5: Authorized Quota vs. Realized Enrollment

Notes: Each dot is a municipality. The horizontal axis shows the federally authorized quota and the vertical axis shows the 12-month average stock of families enrolled in *Bolsa Família*, both per 10,000 residents using fixed 2006 population. The dashed line marks the 45-degree locus of full take-up (realized = authorized). The panels show December 2008, before the mayoral term, and December 2012, at its endpoint. Both axes share a display limit rounded up from the 99th percentile to the next 500-family tick; observations above this limit are excluded from the frame but not from any analysis.

Party Characteristics	✓	✓	✓	✓	✓	✓
Municipality Characteristics		✓		✓		✓
Mayor Characteristics		✓		✓		✓
Number of Mayors	2,078	2,078	2,078	2,078	2,078	2,078
Observations	4,156	4,156	4,156	4,156	4,156	4,156

Notes: All columns use the fixed 2,078-mayor sample, absorb municipality and year effects, use 2006-population weights, and cluster standard errors by state. The quota instrument and registration changes are rates per 10,000 residents using fixed 2006 population. The instrument is reported per one analysis-weighted SD; each endogenous registration measure uses its own fixed analysis-weighted SD; the measure-specific first-stage estimates appear in Table 3. Columns (1), (3), and (5) include 2008 incumbent party, 2006 PT presidential vote share, baseline 2008 program intensity and per-family benefit value, and log 2006 quota. Columns (2), (4), and (6) add municipality and mayor characteristics, including baseline 2008 FPM transfers in the municipality group. Reelection probability is conditional on the incumbent rerunning in 2012. Predetermined controls are interacted with post. Standard errors are in parentheses. Registration expansion counts families first registered in 2009–2012 and still observed in the 2012 *Cadastro Único* snapshot; income and municipality are measured in 2012. These are surviving entry cohorts, not historical net stocks or verified *Bolsa Família* recipients. Income definitions overlap: the at-or-below-R$140 group includes the at-or-below-R$70 group. The reduced form is common across panels. These IVs do not separate registration from subsequent transfers. Anderson–Rubin 95% confidence sets use quadratic state-clustered inversion with a t_{G-1} critical value and are robust to arbitrary instrument weakness. Disconnected two-tail sets use the conservative full-real-line envelope; exact components remain in the result files. Reduced-form stars use null-imposed state wild-cluster bootstrap p-values: $*$ $p < 0.10$, $**$ $p < 0.05$, $***$ $p < 0.01$. † on a 2SLS estimate denotes exclusion of zero by its unrounded AR 95% set.

Observations	4,156	4,156

Notes: All columns absorb municipality and year fixed effects. All columns use 2006-population weights and state-clustered standard errors. The quota instrument and beneficiary-family expansion are rates per 10,000 residents using fixed 2006 population and are reported per one analysis-weighted SD. *Bolsa Família* characteristics include baseline 2008 program intensity, per-family benefit value, and log 2006 quota. Party characteristics include 2008 incumbent party and 2006 PT presidential vote share. Municipality characteristics include baseline 2008 FPM transfers. Predetermined controls are interacted with post. Standard errors are in parentheses. The first column reports reduced-form responses to one analysis-weighted standard deviation of quota exposure; the second reports 2SLS responses to one analysis-weighted standard deviation of beneficiary-family expansion. The first four outcomes are percentages of registered voters and sum to 100; registered voters are per 10,000 residents. Stars on reduced-form estimates denote null-imposed state wild-cluster bootstrap p-values from 9,999 draws: $* p < 0.10$, $** p < 0.05$, $*** p < 0.01$. A dagger denotes a 2SLS coefficient whose unrounded Anderson–Rubin 95% set excludes zero. The displayed Anderson–Rubin sets use quadratic state-clustered inversion; exact components of disconnected sets remain in the result files. Aggregate accounting cannot identify individual voter transitions.

Table 9: Electoral Returns Across Single Control Additions

	Main (1)	*Bolsa Família* (2)	Party (3)	Municipality (4)	Mayor (5)
Panel A: First Stage

Anderson–Rubin 95% confidence sets use quadratic state-clustered inversion with a t_{G-1} critical value and are robust to arbitrary instrument weakness. All columns contain the same 2,078 mayors and 4,156 municipality-year observations. Each nonmain column omits only the named block from the complete main specification.

Table 12: Reverse Causality Channels

	Reverse Causality Channels	
	(1)	(2)
Panel A: Δ Permitted *Bolsa Família* Expansion		
Incumbent's Vote Share in 2008	0.009	-0.005
	(0.018)	(0.016)
Panel B: Δ Realized *Bolsa Família* Expansion		
Incumbent's Vote Share in 2008	-0.058**	-0.049*
	(0.026)	(0.022)
Bolsa Família Characteristics	✓	✓
Party Characteristics	✓	✓
Municipality Characteristics		✓
Mayor Characteristics		✓
Number of Mayors	2,078	2,078
Observations	2,078	2,078

Notes: Panel A measures permitted quota expansion in quota-shock-SD units. Panel B measures the 2008–2012 net change in the 12-month average beneficiary-family stock in treatment-change-SD units. The regressor is the 2008 winner's vote share divided by its analysis-weighted SD of 9.59 percentage points. Every column is weighted by 2006 population and includes state fixed effects. Column (1) includes incumbent-party effects and baseline *Bolsa Família* intensity. Column (2) adds municipality and incumbent-mayor characteristics. These controls are baseline and pre-shock: party, program intensity, and mayor characteristics use 2008 values; population uses 2006; and the remaining municipality characteristics use the 2000 Census. Both columns therefore use only pre-shock controls. Standard errors clustered by state are reported in parentheses. Stars use state wild-cluster bootstrap p-values: $* \; p < 0.10$, $* * \; p < 0.05$, $* * * \; p < 0.01$.

Table 13: Alternative Exclusion Channels

	Alternative Exclusion Channels	
	(1)	(2)
Panel A: Δ FPM Transfers		
ΔQuota_m	0.082	0.107^{***}
	(0.058)	(0.020)
Panel B: Δ Per-Family *Bolsa Família* Benefit Value		
ΔQuota_m	0.049	0.083^{*}
	(0.043)	(0.035)
Bolsa Família Characteristics	✓	✓
Party Characteristics	✓	✓
Municipality Characteristics		✓
Mayor Characteristics		✓
Number of Mayors	2,078	2,078
Observations	4,156	4,156

Notes: Panel A uses the change between the 12-month average of total municipal FPM transfers in 2008 and 2012, per 10,000 residents using fixed 2006 population, divided by its full-sample 2006-population-weighted SD. Panel B uses the change between the simple averages of the twelve monthly per-family benefit values in 2008 and 2012, divided by the cross-municipality SD of its change. The analysis-weighted mean changes are R$57,959.64 per month per 10,000 residents for FPM and R$49.48 per family per month for benefit value. Multiplying the standardized Column (2) quota coefficients by the corresponding outcome SD gives R$5,466.59 per month per 10,000 residents and R$0.91 per family per month, respectively. All models use 2006-population weights and absorb municipality and year effects. Each displayed row is a reduced-form channel diagnostic and is not conditioned on realized beneficiary expansion. Column (1) includes incumbent-party effects and baseline *Bolsa Família* intensity. Column (2) adds municipality and incumbent-mayor characteristics. These controls are baseline and pre-shock: party, program intensity, and mayor characteristics use 2008 values; population uses 2006; and the remaining municipality characteristics use the 2000 Census. Both columns therefore use only pre-shock controls. Standard errors clustered by state are reported in parentheses. Stars use state wild-cluster bootstrap p-values: $* \; p < 0.10$, $* * \; p < 0.05$, $* * * \; p < 0.01$.

Table 14: Heterogeneity by Subgroup: Northeast States and PT Incumbent

	Northeast States			PT Incumbent

Bolsa Família Characteristics	✓	✓		✓	✓	
Party Characteristics	✓	✓		✓	✓	
Municipality Characteristics	✓	✓		✓	✓	
Mayor Characteristics	✓	✓		✓	✓	
Number of Mayors	1,373	705	2,078	1,821	257	2,078
Observations	4,156	4,156	4,156	4,156	4,156	4,156

Notes: All estimated subgroup coefficients absorb municipality and year effects. All use 2006-population weights and state-clustered standard errors. The instrument and endogenous variable are rates per 10,000 residents using fixed 2006 population and are reported per one full-sample analysis-weighted SD. Each subgroup includes 2008 incumbent party, 2006 PT presidential vote share, baseline 2008 program intensity and per-family benefit value, log 2006 quota, and municipality and mayor characteristics, including baseline 2008 FPM transfers in the municipality group. Predetermined controls are interacted with post. Standard errors are in parentheses. Each three-column block uses the full headline sample. Each block is one fully interacted dual-IV regression. The instrument, endogenous variable, and complete control set are allowed to vary across the complementary subgroup indicators; Δ is the first coefficient minus the second. The saturated system reproduces separate subgroup coefficients while retaining one joint model for the displayed comparison. Number of Mayors counts each subgroup (and the full block for the contrast); Observations reports the full sample used by the saturated regression in every column. Contrast columns are calculated from the joint model and therefore do not receive control check marks. First-stage and reduced-form stars use two-sided null-imposed state wild-cluster bootstrap p-values from 9,999 draws, including direct tests of the displayed contrasts: $*\ p < 0.10$, $**\ p < 0.05$, $***\ p < 0.01$. Conditional first-stage F statistics follow Sanderson and Windmeijer (2016). Group AR 95% sets use quadratic state-clustered inversion with a t_{G-1} critical value, conditional on the other group coefficient at its 2SLS estimate. They are not exact joint weak-IV confidence regions. † attached to a subgroup 2SLS estimate denotes that its conditional AR 95% set excludes zero; contrasts have no AR marker.

Table 15: Pre-Reform Vote-Share Balance

	Incumbent's Vote Share in 2008	
	(1)	(2)
ΔQuota_m	0.127	-0.070
	(0.254)	(0.228)
Bolsa Família Characteristics	✓	✓
Party Characteristics	✓	✓
Municipality Characteristics		✓
Mayor Characteristics		✓
Number of Mayors	2,078	2,078
Observations	2,078	2,078

Notes: The dependent variable is the vote share of the mayor elected in 2008, measured before the quota reform. Every column is weighted by 2006 population and includes state fixed effects. The quota shock is a rate per 10,000 residents using fixed 2006 population and is divided by its main-sample analysis-weighted SD. Column (1) includes incumbent-party effects and baseline *Bolsa Família* intensity. Column (2) adds municipality and incumbent-mayor characteristics. These controls are baseline and pre-shock: party, program intensity, and mayor characteristics use 2008 values; population uses 2006; and the remaining municipality characteristics use the 2000 Census. Both columns therefore use only pre-shock controls. Standard errors clustered by state are reported in parentheses. Stars use state wild-cluster bootstrap p-values: $*\ p < 0.10$, $**\ p < 0.05$, $***\ p < 0.01$.

Table 16: Selection into Rerunning

	Incumbent Runs Again in 2012	
	(1)	(2)
ΔQuota_m	-2.183	0.045
	(1.156)	(1.017)
Bolsa Família Characteristics	✓	✓
Party Characteristics	✓	✓
Municipality Characteristics		✓
Mayor Characteristics		✓
Number of Mayors	5,492	5,492
Observations	5,492	5,492

Notes: The dependent variable equals 100 if the mayor elected in 2008 appears on the 2012 ballot and zero otherwise. The estimation universe is constructed before conditioning on rerunning. Every column is weighted by 2006 population and includes state fixed effects because municipality and year effects are not identified in this one-observation-per-mayor design. The quota shock is a rate per 10,000 residents using fixed 2006 population and is divided by the main-sample analysis-weighted SD. Column (1) includes incumbent-party effects and baseline *Bolsa Família* intensity. Column (2) adds municipality and incumbent-mayor characteristics. These controls are baseline and pre-shock: party, program intensity, and mayor characteristics use 2008 values; population uses 2006; and the remaining municipality characteristics use the 2000 Census. Both columns therefore use only pre-shock controls. Standard errors clustered by state are reported in parentheses. Stars use state wild-cluster bootstrap p-values: $*\ p < 0.10$, $**\ p < 0.05$, $***\ p < 0.01$.

Mayor Characteristics	✓	✓	✓	✓	✓	✓	✓
Number of Mayors	2,078	2,078	2,078	2,078	2,078	2,078	2,078
Observations	4,156	4,156	4,156	4,156	4,156	4,156	4,156

Notes: All columns absorb municipality and year effects, use 2006-population weights, and cluster standard errors by state. The instrument and endogenous variable are rates per 10,000 residents using fixed 2006 population and are reported per one analysis-weighted SD, except the per-family normalization in Column (7). All columns include the complete predetermined control set: 2008 incumbent party, 2006 PT presidential vote share, baseline 2008 program intensity and per-family benefit value, log 2006 quota, and municipality and mayor characteristics, including baseline 2008 FPM transfers. These controls are interacted with post. Standard errors are in parentheses. Column (1) is the preferred valid-vote specification. Columns (2)–(3) winsorize the outcome at the 1st and 99th percentiles or divide incumbent votes by registered voters. Column (4) winsorizes the quota shock. Column (5) uses the 2009 authorization shock and the 2008–2009 beneficiary change, each scaled by its own analysis-weighted SD. Column (6) adds IPW to the population weights. Column (7) expresses the instrument and treatment per 100 Census-2000 families. The winsorized quota shock uses its own analysis-weighted SD. First-stage and reduced-form stars use two-sided null-imposed state wild-cluster bootstrap p-values from 9,999 draws: $*\ p < 0.10$, $**\ p < 0.05$, $***\ p < 0.01$. Anderson–Rubin 95% confidence sets use quadratic state-clustered inversion with a t_{G-1} critical value and are robust to arbitrary instrument weakness. † on a 2SLS estimate means its unrounded AR 95% set excludes zero.

Table 18: Continuous-Quota and Discrete-Beneficiary Specifications

Bolsa Família Characteristics	✓	✓	✓	✓	✓	✓
Party Characteristics	✓	✓	✓	✓	✓	✓
Municipality Characteristics		✓		✓		✓
Mayor Characteristics		✓		✓		✓
Number of Mayors	2,078	2,078	2,078	2,078	2,078	2,078
Observations	4,156	4,156	4,156	4,156	4,156	4,156

Notes: All columns absorb municipality and year effects, use 2006-population weights, and cluster standard errors by state. The quota instrument and continuous beneficiary change are rates per 10,000 residents using fixed 2006 population and are reported per one analysis-weighted SD. Columns (1), (3), and (5) include 2008 incumbent party, 2006 PT presidential vote share, baseline 2008 program intensity and per-family benefit value, and log 2006 quota. Columns (2), (4), and (6) add municipality and mayor characteristics, including baseline 2008 FPM transfers in the municipality group. Predetermined controls are interacted with post. Standard errors are in parentheses. The quota shock remains continuous in every panel. Panel B retains continuous beneficiary change; Panels C–E use an indicator that the 2008–2012 change meets or exceeds the headline-sample median, 75th percentile, or 90th percentile, respectively. Their 2SLS coefficients describe crossing the displayed threshold, not a continuous dose response. The reduced form is common across panels and shown once. Reelection probability is conditional on the incumbent rerunning in 2012. Anderson–Rubin 95% confidence sets use quadratic state-clustered inversion with a t_{G-1} critical value and are robust to arbitrary instrument weakness. Reduced-form stars use two-sided null-imposed state wild-cluster bootstrap p-values from 9,999 draws: $*\ p < 0.10$, $**\ p < 0.05$, $***\ p < 0.01$. † on a 2SLS estimate means its unrounded AR 95% set excludes zero.

Bolsa Família Characteristics	✓	✓	✓	✓	✓	✓
Party Characteristics	✓	✓	✓	✓	✓	✓
Municipality Characteristics		✓		✓		✓
Mayor Characteristics		✓		✓		✓

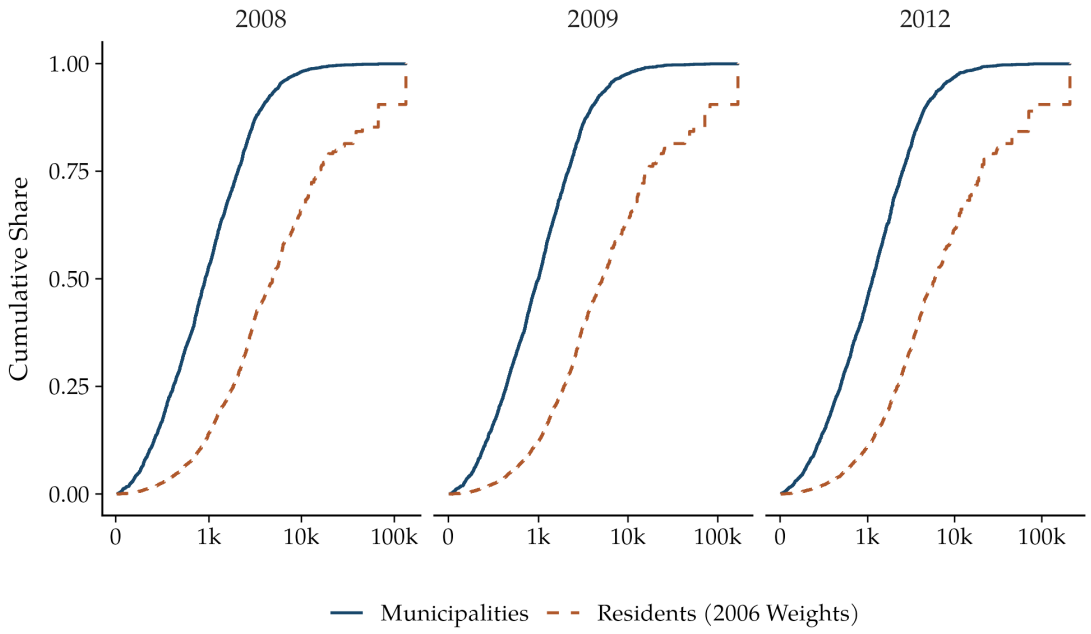

Notes: All columns absorb municipality and year effects. All columns use 2006-population weights and state-clustered standard errors. The instrument and endogenous variable are rates per 10,000 residents using fixed 2006 population and are reported per one analysis-weighted SD. Column (1) includes 2008 incumbent party, 2006 PT presidential vote share, baseline 2008 program intensity and per-family benefit value, and log 2006 quota. Column (2) adds municipality and mayor characteristics, including baseline 2008 FPM transfers in the municipality group. Predetermined controls are interacted with post. Standard errors are in parentheses. The Column (1)–(2) control sequence repeats in Columns (3)–(4) and (5)–(6). Reelection probability is conditional on the incumbent rerunning in 2012. Anderson–Rubin 95% confidence sets use quadratic state-clustered inversion with a t_{G-1} critical value and are robust to arbitrary instrument weakness. Reduced-form stars use two-sided null-imposed state wild-cluster bootstrap p-values from 9,999 draws: $*\ p < 0.10$, $**\ p < 0.05$, $***\ p < 0.01$. † on a 2SLS estimate means its unrounded AR 95% set excludes zero. Panels use the 2006-population median, 75th percentile, and 90th percentile calculated in the headline sample. Below-median is nested within below-75th; above-90th is nested within above-75th, which is nested within above-median. Models are estimated separately within each displayed subsample; the panels are not mutually exclusive.

Figure 6: Distribution of 2006 Population in the Main Sample

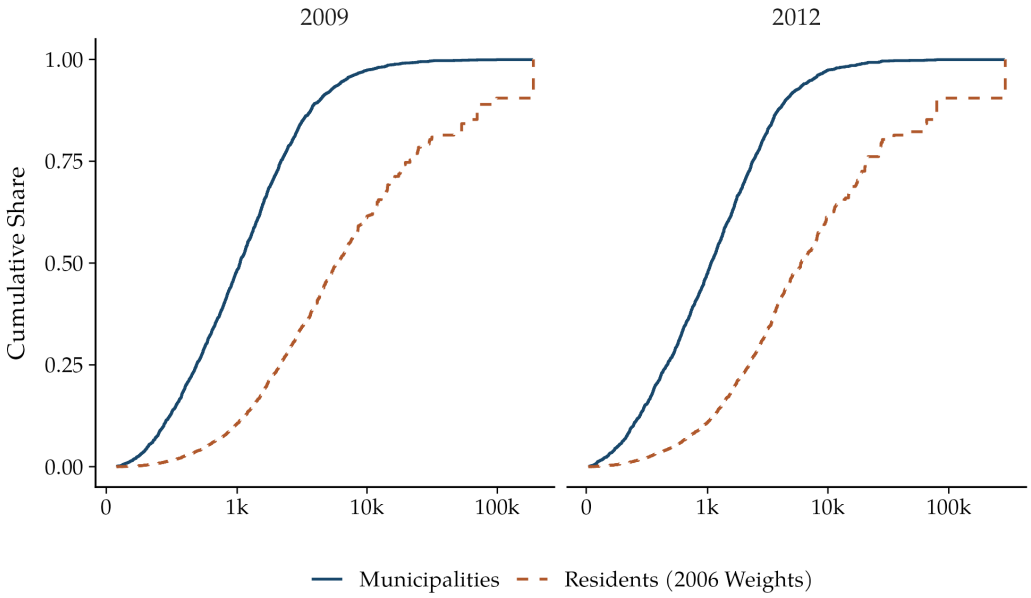

Notes: The sample contains the 2,078 municipalities whose 2008 winners sought reelection in 2012 and meet the complete-case requirements of the main analysis. The solid curve gives each municipality equal weight; the dashed curve weights municipalities by their fixed 2006 population. The horizontal axis uses a pseudo-log scale while labels report resident counts. These are descriptive cumulative distributions, not estimates of policy effects.

Figure 7: Distribution of Beneficiary-Family Stocks in the Main Sample

Notes: Each panel shows the cumulative distribution of the 12-month average number of families receiving *Bolsa Família* at the December endpoint in the indicated year, for the same 2,078 municipalities. The solid curve weights municipalities equally; the dashed curve uses fixed 2006 population weights. The pseudo-log horizontal scale displays family counts, not a log-rate transformation. Stocks at different endpoints do not by themselves measure program-induced enrollment.

Figure 8: Distribution of Authorized Quotas in the Main Sample

Notes: Each panel shows the federally authorized number of *Bolsa Família* family places at the 2009 or 2012 endpoint in the locked main-analysis municipalities. The solid curve weights municipalities equally; the dashed curve uses fixed 2006 population weights. The pseudo-log horizontal scale displays family counts. These quota stocks are descriptive and differ from the counterfactual-adjusted authorization shock used as the instrument.

Table 20: Heterogeneity by Subgroup: Frey-like Group and Baseline *Bolsa Família* Intensity

Conditional AR 95% CI	[7.458, 35.872]	[-1.779, 1.628]		[2.877, 22.948]	[-1.676, 1.377]	
Bolsa Família Characteristics	✓	✓		✓	✓	
Party Characteristics	✓	✓		✓	✓	
Municipality Characteristics	✓	✓		✓	✓	
Mayor Characteristics	✓	✓		✓	✓	
Number of Mayors	343	1,735	2,078	1,039	1,039	2,078
Observations	4,156	4,156	4,156	4,156	4,156	4,156

Notes: All estimated subgroup coefficients absorb municipality and year effects. All use 2006-population weights and state-clustered standard errors. The instrument and endogenous variable are rates per 10,000 residents using fixed 2006 population and are reported per one full-sample analysis-weighted SD. Each subgroup includes 2008 incumbent party, 2006 PT presidential vote share, baseline 2008 program intensity and per-family benefit value, log 2006 quota, and municipality and mayor characteristics, including baseline 2008 FPM transfers in the municipality group. Predetermined controls are interacted with post. Standard errors are in parentheses. Each three-column block uses the full headline sample. The Frey-like group uses 2000 population below 30,000 and 2000 HDI below 0.7. Frey's original funding rule used 2003 population estimates. Each block is one fully interacted dual-IV regression. The instrument, endogenous variable, and complete control set are allowed to vary across the complementary subgroup indicators; Δ is the first coefficient minus the second. The saturated system reproduces separate subgroup coefficients while retaining one joint model for the displayed comparison. Number of Mayors counts each subgroup (and the full block for the contrast); Observations reports the full sample used by the saturated regression in every column. Contrast columns are calculated from the joint model and therefore do not receive control check marks. First-stage and reduced-form stars use two-sided null-imposed state wild-cluster bootstrap p-values from 9,999 draws, including direct tests of the displayed contrasts: $*\ p < 0.10$, $**\ p < 0.05$, $***\ p < 0.01$. Conditional first-stage F statistics follow Sanderson and Windmeijer (2016). Group AR 95% sets use quadratic state-clustered inversion with a t_{G-1} critical value, conditional on the other group coefficient at its 2SLS estimate. They are not exact joint weak-IV confidence regions. † attached to a subgroup 2SLS estimate denotes that its conditional AR 95% set excludes zero; contrasts have no AR marker.

Municipality Characteristics	✓	✓		✓	✓		✓	✓	
Mayor Characteristics	✓	✓		✓	✓		✓	✓	
Number of Mayors	2,078	2,078	2,078	2,078	2,078	2,078	2,078	2,078	2,078
Observations	4,156	4,156	4,156	4,156	4,156	4,156	4,156	4,156	4,156

Notes: All columns absorb municipality and year fixed effects. All columns use 2006-population weights and state-clustered standard errors. The instrument and endogenous variable are rates per 10,000 residents using fixed 2006 population and are reported per one analysis-weighted SD. Party characteristics include 2008 incumbent party and 2006 PT presidential vote share. *Bolsa Família* characteristics include baseline 2008 program intensity, per-family benefit value, and log 2006 quota. Municipality characteristics include baseline 2008 *FPM* transfers. Predetermined controls are interacted with post. Standard errors are in parentheses. Reelection probability is conditional on the incumbent rerunning in 2012. † on a subgroup 2SLS estimate denotes exclusion of zero by its unrounded conditional AR 95% set; contrasts have no marker. Each outcome is estimated in one fully interacted dual-IV system allowing the standardized instrument, treatment, and complete control set to vary with 2008 *CRAS* presence and its complement; no CRAS record means no baseline census record, not verified absence of an office. Δ is the first coefficient minus the second. The saturated system reproduces separate subgroup coefficients while retaining one joint model for the displayed comparison. Conditional first-stage F statistics follow Sanderson and Windmeijer (2016). AR sets are plug-in conditional diagnostics, not exact joint weak-IV regions.

Notes: The two municipality groups partition the locked headline sample by CRAS presence before the reform. The four information panels repeat for both groups. Variables, scaling, and unweighted summary statistics match the main descriptive table; N counts nonmissing municipalities. The table includes baseline characteristics and the explicitly dated program and electoral outcomes shown in that table. Differences are descriptive, not estimates of the effect of CRAS.

Observations	2,788	2,788	2,788	2,788	2,788	2,788	2,788	2,788	2,788

Notes: All columns absorb municipality and year fixed effects. All columns use 2006-population weights and state-clustered standard errors. The instrument and endogenous variable are rates per 10,000 residents using fixed 2006 population and are reported per one analysis-weighted SD. Party characteristics include 2008 incumbent party and 2006 PT presidential vote share. *Bolsa Família* characteristics include baseline 2008 program intensity, per-family benefit value, and log 2006 quota. Municipality characteristics include baseline 2008 *FPM* transfers. Predetermined controls are interacted with post. Standard errors are in parentheses. Reelection probability is conditional on the incumbent rerunning in 2012. † on a subgroup 2SLS estimate denotes exclusion of zero by its unrounded conditional AR 95% set; contrasts have no marker. Each outcome is estimated within 2008 *CRAS* municipalities in one fully interacted dual-IV system comparing units with and without active outreach; Δ is Without Active Outreach minus With Active Outreach. The instrument, treatment, and complete control set can vary across the two groups. Conditional first-stage F statistics follow Sanderson and Windmeijer (2016). AR sets are plug-in conditional diagnostics, not exact joint weak-IV regions. Groups are predetermined scope conditions, not causal effects of adopting outreach.

Number of Mayors	684	831	563	684	831	563	684	831	563
Observations	1,368	1,662	1,126	1,368	1,662	1,126	1,368	1,662	1,126

Notes: All columns absorb municipality and year fixed effects. All columns use 2006-population weights and state-clustered standard errors. The quota instrument and beneficiary-family expansion are rates per 10,000 residents using fixed 2006 population and are reported per one analysis-weighted SD. *Bolsa Família* characteristics include baseline 2008 program intensity, per-family benefit value, and log 2006 quota. Party characteristics include 2008 incumbent party and 2006 PT presidential vote share. Municipality characteristics include baseline 2008 FPM transfers. Predetermined controls are interacted with post. Standard errors are in parentheses. The three CRAS-age groups are estimated separately. Opening years come from the baseline census; missing dates are excluded. No CRAS record denotes no baseline census record, not verified absence of an office. The reported Kleibergen–Paap F is the just-identified excluded-instrument state-clustered Wald statistic. First-stage and reduced-form stars use null-imposed state wild-cluster bootstrap p-values from 9,999 draws: $*\ p < 0.10$, $**\ p < 0.05$, $***\ p < 0.01$. Anderson–Rubin 95% confidence sets use quadratic state-clustered inversion with a t_{G-1} critical value and are robust to arbitrary instrument weakness. † on a 2SLS estimate denotes exclusion of zero by its unrounded AR set. Disconnected two-tail sets use their conservative full-real-line envelope; exact components remain in the result files. Reelection probability is conditional on the incumbent rerunning in 2012. Subgroup comparisons are descriptive, not causal effects of CRAS.

Table 27: Descriptive Quota Responses Across CRAS Adoption Cohorts

Bolsa Família Characteristics	✓	✓	✓	✓	✓
Party Characteristics	✓	✓	✓	✓	✓
Municipality Characteristics	✓	✓	✓	✓	✓
Mayor Characteristics	✓	✓	✓	✓	✓

Notes: All columns absorb municipality and year fixed effects. All columns use 2006-population weights and state-clustered standard errors. The quota instrument and beneficiary-family expansion are rates per 10,000 residents using fixed 2006 population and are reported per one analysis-weighted SD. *Bolsa Família* characteristics include baseline 2008 program intensity, per-family benefit value, and log 2006 quota. Party characteristics include 2008 incumbent party and 2006 PT presidential vote share. Municipality characteristics include baseline 2008 FPM transfers. Predetermined controls are interacted with post. Standard errors are in parentheses. The five cohort slopes are from fully interacted reduced-form models on the common 1,917-mayor (3,834-observation) sample; Number of Mayors shows cohort support, while Observations shows the full jointly estimated sample. Registration and enrollment are rates per 10,000 residents; electoral outcomes are percentage points. Pointwise 95% intervals use the state-clustered covariance and a t_{G-1} critical value. Stars denote null-imposed state wild-cluster bootstrap p-values from 9,999 draws: $*$ $p < 0.10$, $**$ $p < 0.05$, $***$ $p < 0.01$. This test is unavailable for the separately reconstructed reelection column, which therefore receives no markers. Later cohorts use dates reported by offices observed in 2012 and condition on post-reform choices, so these comparisons are descriptive. No 2012 census record does not mean verified absence of an office. Reelection probability is conditional on the incumbent rerunning in 2012. Contrasts and adjusted tests remain in the analysis sidecars.

Mayor Characteristics		✓
Number of Mayors	2,078	2,078
Observations	2,078	2,078

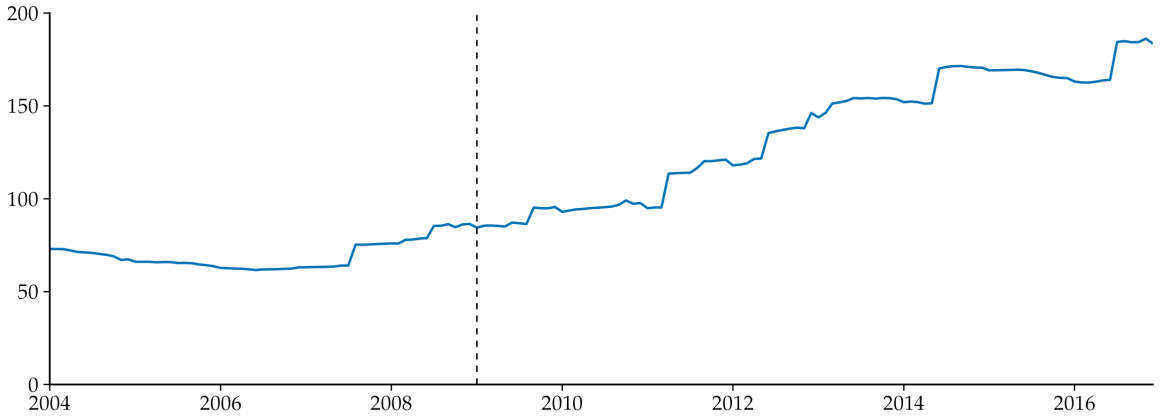

Notes: Each panel estimates separate slopes for the named upper-tail group and its complement on the full locked sample; the table reports the upper-tail slope. Groups are defined by unweighted quota-shock quantiles and are nested. All models include state fixed effects, 2006-population weights, and state-clustered standard errors. Columns (1)–(2) follow the pre-treatment control sequence. Stars use state wild-cluster bootstrap p-values: $*\ p < 0.10$, $**\ p < 0.05$, $***\ p < 0.01$. This is an average first-stage-shape diagnostic, not a test of unit-level monotonicity.

Figure 9: Monthly *Bolsa Família* Payments

Panel A: Monthly Payments (BRL billions)

Panel B: Monthly Payments per Family (BRL)

Notes: Totals cover the same 2,078 headline municipalities throughout, rather than Brazil as a whole. Payments are nominal BRL; the mean benefit is aggregate payments divided by beneficiary families. The series retains the existing data-construction corrections for isolated payment spikes. The dashed line marks the year 2009, not the implementation month. Source: MDS monthly municipal program records, distinct from the 2012 family-registration snapshot.

	(0.155)	(0.131)	(0.180)	(0.172)
Bolsa Família Characteristics	✓	✓	✓	✓
Party Characteristics	✓	✓	✓	✓
Municipality Characteristics	✓	✓	✓	✓
Mayor Characteristics	✓	✓	✓	✓
Number of Mayors	2078	684	1394	2078
Observations	4,156	4,156	4,156	4,156

Notes: All columns absorb municipality and year fixed effects. All columns use 2006-population weights and state-clustered standard errors. The quota instrument and beneficiary-family expansion are rates per 10,000 residents using fixed 2006 population and are reported per one analysis-weighted SD. *Bolsa Família* characteristics include baseline 2008 program intensity, per-family benefit value, and log 2006 quota. Party characteristics include 2008 incumbent party and 2006 PT presidential vote share. Municipality characteristics include baseline 2008 FPM transfers. Predetermined controls are interacted with post. Standard errors are in parentheses. Coefficients report responses to one fixed headline-sample weighted SD of quota exposure. The top header and Panels A–D report Δ registrations; Panels E–F report complementary program responses. First registrations count families first registered in 2009–2012 that survive in the 2012 snapshot; beneficiary families measure the change in the 12-month average stock receiving *Bolsa Família*; monthly payments per resident measure the transfer flow. These are distinct outcomes, not sequentially verified states of the same families. Registration and beneficiary-family quantities are per 10,000 fixed 2006 residents; payments are nominal monthly BRL per resident. Income is classified in the 2012 snapshot. Stars use Holm-adjusted null-imposed state wild-cluster bootstrap p-values across the six outcomes in each column, using 9,999 draws: $*\ p < 0.10$, $**\ p < 0.05$, $***\ p < 0.01$. The Main column fits a common-slope specification on the displayed analysis sample. The Δ column is w/ minus w/o from the interacted specification. Number of Mayors counts each subgroup; Observations gives the full jointly estimated sample. No CRAS record means no baseline census record, not verified absence of an office.

Mayor Characteristics	✓	✓	✓	✓
Number of Mayors	1394	432	962	1394
Observations	2,788	2,788	2,788	2,788

Notes: All columns absorb municipality and year fixed effects. All columns use 2006-population weights and state-clustered standard errors. The quota instrument and beneficiary-family expansion are rates per 10,000 residents using fixed 2006 population and are reported per one analysis-weighted SD. *Bolsa Família* characteristics include baseline 2008 program intensity, per-family benefit value, and log 2006 quota. Party characteristics include 2008 incumbent party and 2006 PT presidential vote share. Municipality characteristics include baseline 2008 FPM transfers. Predetermined controls are interacted with post. Standard errors are in parentheses. Coefficients report responses to one fixed headline-sample weighted SD of quota exposure. The top header and Panels A–D report Δ registrations; Panels E–F report complementary program responses. First registrations count families first registered in 2009–2012 that survive in the 2012 snapshot; beneficiary families measure the change in the 12-month average stock receiving *Bolsa Família*; monthly payments per resident measure the transfer flow. These are distinct outcomes, not sequentially verified states of the same families. Registration and beneficiary-family quantities are per 10,000 fixed 2006 residents; payments are nominal monthly BRL per resident. Income is classified in the 2012 snapshot. Stars use Holm-adjusted null-imposed state wild-cluster bootstrap p-values across the six outcomes in each column, using 9,999 draws: $*\ p < 0.10$, $**\ p < 0.05$, $***\ p < 0.01$. The Main column fits a common-slope specification on the displayed analysis sample. The Δ column is w/ minus w/o from the interacted specification. Number of Mayors counts each subgroup; Observations gives the full jointly estimated sample. No PAIF count means no positive reported count of *Bolsa Família* families served within baseline CRAS municipalities; missing counts retain the canonical zero coding. This proxy is not a verified contact-frequency measure or verified absence of PAIF.

Figure 10: Annual Registration Responses by Baseline CRAS

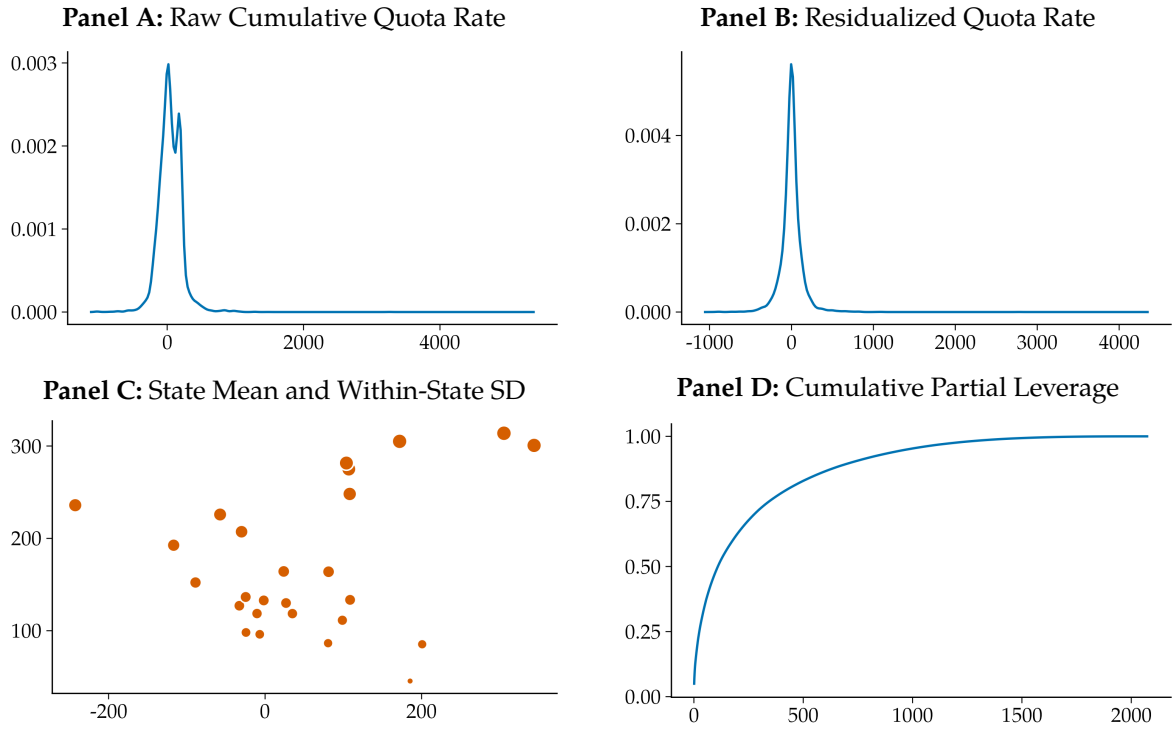

Notes: Each point is the quota-related response of the indicated registration cohort, per 10,000 residents, for municipalities with or without a recorded CRAS before the reform. The two panels use separate authorization measures, each scaled by its own full-sample population-weighted standard deviation. Bars are pointwise state-clustered 95% confidence intervals. Table F.19 reports the group contrasts and multiplicity-adjusted bootstrap tests. Families are observed retrospectively in the 2012 snapshot. Panel B decomposes the cumulative main response by registration year; it does not imply that a future quota change caused earlier registrations. The available aggregates cannot identify pre-2009 monthly trends or families that exited the registry.

Table 32: Electoral Returns and Household Transfers: Conditional Registration Scenarios

	Estimated	Assumed Registration-Dependent Share			
	Quota Response (1)	0% (2)	25% (3)	50% (4)	100% (5)
Panel A: Family Registrations					
Response / Assumed Reduction	48.47*** (9.47)	48.47	48.47	48.47	48.47
95% CI	[28.98, 67.97]	[28.98, 67.97]	[28.98, 67.97]	[28.98, 67.97]	[28.98, 67.97]
Panel B: Beneficiary Families					
Response / Assumed Reduction	62.14*** (9.66)	0.00	15.53	31.07	62.14
95% CI	[42.25, 82.03]	[0.00, 0.00]	[10.56, 20.51]	[21.12, 41.02]	[42.25, 82.03]
Panel C: Monthly Transfers (BRL)					
Response / Assumed Reduction	9,929.11*** (1,549.96)	0.00	2,482.28	4,964.56	9,929.11
95% CI	[6,736.91, 13,121.31]	[0.00, 0.00]	[1,684.23, 3,280.33]	[3,368.45, 6,560.66]	[6,736.91, 13,121.31]
Panel D: Incumbent Vote Share					
Response / Assumed Reduction	1.06** (0.38)	0.00	0.26	0.53	1.06
95% CI	[0.27, 1.84]	[0.00, 0.00]	[0.07, 0.46]	[0.14, 0.92]	[0.27, 1.84]
Number of Mayors	2,078				
Observations	4,156				

Notes: Column (1) estimates responses to 171.50 additional quota slots per 10,000 residents, using full baseline controls, municipality/year effects, 2006-population weights and state-clustered standard errors (parentheses). Intervals are pointwise conventional 95% intervals, not Anderson–Rubin sets. Stars on estimated responses use null-imposed state wild-cluster bootstrap p-values after Holm adjustment across the four outcomes (9,999 draws): $*\ p < 0.10$, $**\ p < 0.05$, $***\ p < 0.01$; scenario values are assumptions, not estimates. Registrations are surviving 2009–2012 entry cohorts in the 2012 snapshot; beneficiary counts and monthly payments use annual averages. Panels A–C are per 10,000 residents; payments are nominal BRL and votes are percentage points. In Panel A, the value 48.47 in columns (2)–(5) is the assumed reduction in new registrations under full suppression, not a remaining registration response. For each other outcome, the assumed share multiplies column (1); matching shares across outcomes are illustrative, not estimated. Zero permits gains through other channels, including previously registered families; 100% assumes all gains depend on new registrations. Conditional intervals treat these shares as fixed. These scenarios do not identify mediation or the effect of removing political incentives. Transfers are municipal totals, not payments linked to new registrants, total household income, cumulative transfers or welfare.

Figure 11: Quota Support, Within-State Variation, and Partial Leverage

Notes: The locked headline sample has 2,078 municipalities and uses 2006-population weights. Panel B partials out the full predetermined headline controls, incumbent-party indicators, and state indicators. Partial leverage is proportional to weighted squared residual quota exposure. The figure diagnoses concentration and does not define an observation-deletion rule.
